

# All-sky search for long-duration gravitational-wave bursts in the third Advanced LIGO and Advanced Virgo run

LIGO Scientific Collaboration, Virgo Collaboration, and KAGRA Collaboration  
(compiled October 1, 2021)

After the detection of gravitational waves from compact binary coalescences, the search for transient gravitational-wave signals with less well-defined waveforms for which matched filtering is not well-suited is one of the frontiers for gravitational-wave astronomy. Broadly classified into “short”  $\lesssim 1$  s and “long”  $\gtrsim 1$  s duration signals, these signals are expected from a variety of astrophysical processes, including non-axisymmetric deformations in magnetars or eccentric binary black hole coalescences. In this work, we present a search for long-duration gravitational-wave transients from Advanced LIGO and Advanced Virgo’s third observing run from April 2019 to March 2020. For this search, we use minimal assumptions for the sky location, event time, waveform morphology, and duration of the source. The search covers the range of 2 – 500 s in duration and a frequency band of 24 – 2048 Hz. We find no significant triggers within this parameter space; we report sensitivity limits on the signal strength of gravitational waves characterized by the root-sum-square amplitude  $h_{\text{rss}}$  as a function of waveform morphology. These  $h_{\text{rss}}$  limits improve upon the results from the second observing run by an average factor of 1.8.

## I. INTRODUCTION

The third observing run of the Advanced LIGO [1] and Advanced Virgo [2] detectors has revealed a large number of new gravitational-wave signals from the collision of compact objects. Many binary black hole systems [3] have been identified. These include GW190521 [4] with the largest progenitor masses discovered so far, and GW190814, a merger containing an object in the “mass-gap” between neutron stars and black holes [5]. A second binary neutron star (BNS) system was also discovered, GW190425 [6], following the first BNS system GW170817 [7], which also produced GRB 170817A [8] and an optical transient, AT 2017gfo [9]. In addition, two neutron star-black hole (NSBH) binary coalescences (GW200105.162426 and GW200115.042309) have also been detected [10].

Searches for “long”  $\gtrsim 1$  s duration signals cover a variety of astrophysical phenomena [11]. While well-modeled compact binary coalescences can have similar durations in the sensitive band of the interferometers and the methods employed in this paper are also sensitive to them, this search is not aimed at these systems as matched filtering is much more sensitive. However, there are less well-defined waveforms for which matched filtering is not well-suited. Plausible processes include fallback accretion onto a rapidly rotating black hole [12] or in newborn neutron stars [13–15]. They also include non-axisymmetric deformations in magnetars [16] or accretion disk instabilities and fragmentation of material spiraling into a black hole [17–19] and in the central engine of super-luminous supernovae [20, 21]. Figure 1 shows several different realizations of the corresponding waveform morphologies.

In this paper, we present the results of unmodeled long-duration transient searches from the third observing run, updating the results from the first two observing runs [22, 23]. As in previous analyses [22–25], three pipelines are used; their different assumptions and data handling techniques yield complementary coverage of the

signal models.

The paper is organized as follows. The data used in the analysis is described in Section II. The algorithms used to analyze the data are outlined in Section III. The results of the analysis and their implications are discussed in Section IV.

## II. DATA

The third observing run (O3) of Advanced LIGO and Advanced Virgo spanned April 1, 2019 - March 27, 2020. O3 was broken up into two segments, with O3a running April 1, 2019 - Oct 1, 2019 and O3b running November 1, 2019 - March 27, 2020; together, these correspond to 330 days. It is customary to assess detector sensitivities in terms of a binary neutron star inspiral range (BNS range), which is the average distance to which these signals could be detected [28, 29]. Detector upgrades to the LIGO detectors in Hanford, WA and Livingston, LA yielded binary neutron star ranges of  $\sim 115$  Mpc and 133 Mpc respectively, amounting to improvements of  $\sim 50\%$  with respect to O2. Similarly, Advanced Virgo reached a binary neutron star range of  $\sim 50$  Mpc, a  $\sim 100\%$  improvement. In the following, the algorithms employed require at least two detectors to be available to process the data; therefore, only data where both LIGO detectors are simultaneously available is used. Due to the significant difference in detector alignment and sensitivities, the Virgo data in the analysis would not improve the coincidence selection when the other two detectors are active, while the high rate of non-Gaussian noise would increase the overall false-alarm rate. We plan to include Virgo in the analysis of the next observing run.

A major challenge in searches for gravitational-wave transients is non-Gaussian noise. Known sources of noise, including non-linear sources such as time-varying spectral lines, from, e.g., machinery on-site, side-bands from the 60 Hz power lines, can be witnessed and subtracted

FIG. 1. Time-frequency spectrogram of the reference waveforms used in this search. We show examples of astrophysical waveforms such as post-merger magnetars (Magnetar) [26], black hole accretion disk instabilities (ADI) [18], newly formed magnetar powering a gamma-ray burst plateau (GRBplateau) [16], eccentric inspiral-merger-ringdown compact binary coalescence waveforms (ECBC) [27], broadband chirps from innermost stable circular orbit waves around rotating black holes (ISCOchirp) [12], and “ad-hoc” waveforms, band-limited white noise burst (WNB) and sine-Gaussian bursts (SG). The ISCOChirp waveforms have been shifted up in frequency by 50 Hz for readability. Durations range from 6 s (ADI-B) to 470 s (GRBplateau).

92 using both linear Wiener filters [30] and machine learn- 117  
 93 ing techniques [31, 32]. The analyses that follow use 118  
 94 data for which some of the identified sources of noise 119  
 95 that couple in linearly to the detector have been sub- 120  
 96 tracted. Beyond spectral features, there are transient 121  
 97 noise triggers known as *glitches*, which have a variety of 122  
 98 origins [33], such as the light reflected from surfaces such 123  
 99 as the chamber walls and scattered back into the main 124  
 100 beam [34]. Glitch rejection procedures rely on correla- 125  
 101 tions with auxiliary channels [35, 36] such as seismome- 126  
 102 ters and magnetometers; yet, noise transients not wit- 127  
 103 nessed by auxiliary sensors remain and reduce sensitivity 128  
 104 of the searches [37, 38]. Each pipeline, described in the 129  
 105 next section, implements different strategies to reduce 130  
 106 the impact from glitches. Altogether, during the third 131  
 107 observing run, coincident data of sufficient quality to be 132  
 108 analyzed totaled 204.4 days. Since some time segments 133  
 109 are too short to be processed by search pipelines, a small 134  
 110 fraction ( $< 2\%$ ) of this coincident data is not analyzed. 135

### 111 III. SEARCHES

112 Long-duration unmodeled searches are now briefly re- 140  
 113 viewed, and we refer the reader to previous publications 141  
 114 for further detail [22, 23]. Most unmodeled searches 142  
 115 use time-frequency spectrograms with statistics derived 143  
 116 from Fourier transforms or wavelet analysis performed 144

on consecutive time segments. Pattern-recognition al-  
 gorithms then are employed to search for gravitational  
 waves in these spectrograms. These algorithms can  
 be classified as: “seed-based” [39, 40], for which pix-  
 els above pre-determined thresholds are clustered, and  
 “seedless” [41, 42], for which sequences of pixels are de-  
 rived from generic models, such as Bézier curves [41–45].  
 Seedless clustering algorithms are sensitive to narrow-  
 band signals at the price of sensitivity to broadband  
 sources, while seed-based algorithms are generally more  
 sensitive to more generic waveform morphologies. These  
 algorithms identify candidate gravitational-wave events  
 known as *triggers*. To estimate the background, all  
 pipelines use “time-slides,” [46, 47], where detector data  
 is shifted by non-physical time delays and reanalyzed;  
 this procedure is repeated a sufficient number of times  
 such that at least 50 years of coincident live time is ana-  
 lyzed, allowing for a false alarm rate of 1 per 50 years to  
 be estimated.

136 Three pipelines are deployed in the analysis: two differ-  
 137 ent versions of the Stochastic Transient Analysis Multi-  
 138 detector Pipeline - all sky (STAMP-AS) pipeline [11,  
 139 40, 45] and the long-duration configuration of coherent  
 140 WaveBurst (cWB) [48]. The cWB pipeline is seed-based  
 141 while the two STAMP-AS algorithms, ZebraGard and  
 142 Lonetrack, use seed-based and seedless clustering algo-  
 143 rithms respectively. Altogether, the analyses are sensi-  
 144 tive to transients lasting 2 – 500 s and covering a fre-

quency band of 24 – 2048 Hz. Due to the short duration of binary black hole signals and the weakness of the coalescences containing neutron stars observed during O3 [6], we are not sensitive to and therefore do not excise any time around known compact binary coalescences. All false alarm rates reported are per pipeline, with no combination of searches made outside of reporting the most sensitive limit across the parameter space below.

*STAMP-AS.* Spectrograms, with duration 500 s and frequency band 24 – 2048 Hz and a pixel size of 1 s × 1 Hz, are derived with cross-power SNR as the statistic computed in the maps. Non-stationary, high-amplitude spectral features are masked to limit their effect on the search. Zebragard uses cuts on the fraction of SNR per time bin (summing all pixels of the same time index) and the ratio in SNR between detectors to remove data transients [22]; Lonetrack does not require this cut due to the narrowband assumption. During a short period of time, a time segment veto that flags periods of instabilities in the high-power laser at Hanford is applied on Zebragard triggers [38].

*cWB.* The algorithm used by cWB [48] is based on a maximum likelihood approach applied to the multiresolution time-frequency representation of the time series of the detectors’ data. Candidate triggers are identified as a cluster if there is a coherent excess power in the time-frequency pixel representation over the network data. The search is performed in the frequency range 24 – 2048 Hz. Selection criteria are applied on the duration and on the coherence of the trigger; the coherence coefficient, measuring the degree of correlation between the detectors, must be larger than 0.6 [48]. Moreover, the trigger energy-weighted duration, defined as

$$d = \sqrt{\frac{\sum w_i (t - t^*)^2}{\sum w_i}},$$

where  $t$  is the central time of the pixel,  $w$  the energy of the pixel,  $t^*$  the mean time and the sum is computed over the selected pixels of the event in all the resolutions, is required to be greater than 1.5 s. Since observed glitch excess in the 16 – 48 Hz band, associated with elevated anthropogenic noise, is different between the first and second part of the run, the acceptance criteria in the latter one have been slightly modified. The triggers have an energy-weighted duration larger than 0.5 s and a total duration greater than 5 s, this to ensure increased acceptance for the eccentric compact binary waveforms family discussed in the next section.

#### IV. RESULTS AND FUTURE PROSPECTS

The detection threshold is defined to be a false alarm rate lower than 1/50 years (equivalent to  $6.3 \times 10^{-10}$  Hz). None of the pipelines found triggers consistent with such a false alarm rate; the most significant triggers, non-

Pipeline	FAR [Hz]	p-value	Frequency [Hz]	Duration [s]	Time [GPS]
cWB	$1.0 \times 10^{-8}$	0.088	838-861	16	1252808855
Zebragard	$5.6 \times 10^{-8}$	0.40	1650-1769	21	1244819393
Lonetrack	$1.7 \times 10^{-8}$	0.14	1510-1937	417	1253105020

TABLE I. Properties of the most significant coincident triggers found by each of the long-duration transient search pipelines during the third observing run. FAR stands for false alarm rate, while the p-value is the probability of observing at least 1 noise trigger at higher significance than the most significant coincident trigger.

overlapping between the different pipelines and consistent with the background, are listed in Table I. The most significant event reported by the cWB algorithm (statistical significance  $\sim 1.7 \sigma$ , p-value 0.088) shows a time-frequency map composed of two separated excess power cluster pixels, respectively, at 838 Hz and 861 Hz mean frequency. This trigger appears to be associated with a random (time) coincidence of pixels belonging to two different non-stationary spectral lines of unknown origin, at 838 Hz (present in H1 and L1) and 861 Hz (present in H1). The STAMP-AS Zebragard and Lonetrack pipeline triggers are consistent with typical events identified in the background.

To place these results in context, upper limits are derived on the gravitational-wave strain amplitude using a set of simulated waveforms added coherently into detector data. Waveforms that span the parameter space in both frequency and time, as well as a sampling of potential astrophysical models, are used. For the astrophysical models, post-merger magnetars (Magnetar) [26], black hole accretion disk instabilities (ADI) [18], newly formed magnetar powering a gamma-ray burst plateau (GRBplateau) [16], eccentric inspiral-merger-ringdown compact binary coalescence waveforms (ECBC) [27], and broadband chirps from innermost stable circular orbit waves around rotating black holes (ISCOchirp) [12] are used (see Ref. [49] for further developments). To include signal morphologies otherwise not addressed by the astrophysical models, “ad-hoc” waveforms, band-limited white noise burst (WNB) and sine-Gaussian bursts (SG) are also used. Their time-frequency spectrograms are shown in Figure 1.

The upper limits on the gravitational-wave strain amplitude are typically reported for unmodeled searches using the root-sum-square gravitational-wave amplitude at the Earth,  $h_{\text{rss}}$ ,

$$h_{\text{rss}} = \sqrt{\int_{-\infty}^{\infty} (h_+^2(t) + h_\times^2(t)) dt}, \quad (1)$$

where  $h_+$  and  $h_\times$  are the two signal polarizations. Simulations are varied with  $h_{\text{rss}}$  and injected uniformly in time, sky location, polarization angle and the cosine of the inclination angle of the assumed source.

FIG. 2. The GW root-sum-square strain amplitude versus mean frequency at 50% detection efficiency and a FAR of 1/50 years. The red, green and blue curves are the averaged amplitude spectral noise densities for Hanford, Livingston and Virgo detectors to show that the search results follow the detectors’ sensitivity frequency. We also show in dashed-dotted lines the gravitational-wave amplitudes corresponding to the energy of  $0.01 M_{\odot}c^2$  at various distances, with examples at 100 kpc, 1 Mpc, 10 Mpc and 100 Mpc shown.

235 Upper limits on gravitational-wave strain versus mean  
 236 frequency for sources detected with 50% efficiency and  
 237 a false alarm rate of 1 event in 50 years are shown in  
 238 Figure 2. The strongest bounds obtained from the three  
 239 pipelines are shown on the plot. Because each pipeline  
 240 uses a different clustering algorithm, their relative sensi-  
 241 tivities vary with waveform morphology. Lonetrack,  
 242 which uses seedless clustering, performs best on magne-  
 243 tar signals (Magnetar and GRBplateau) but is not sensi-  
 244 tive to white noise bursts. Zebragard and Coherent  
 245 WaveBurst give the most constraining values with simi-  
 246 lar sensitivities for most of the remaining waveforms. On  
 247 average, for all waveforms considered in this paper, the  
 248  $h_{\text{rSS}}$  sensitivity improved by a factor of 1.8 upon the anal-  
 249 ysis from the second observing run [23].

250 For the eccentric binary waveforms, we determine 90%  
 251 confidence level limits on the rate of events. We do this  
 252 using the “loudest event statistic” method, which uses  
 253 the candidate with the largest value to estimate rate con-  
 254 straints [50]. Taking as an example the eccentric binary  
 255 waveforms, the 90% upper limits on the event rates as a  
 256 function of distance are highlighted in Figure 3. In ad-  
 257 dition, Table II gives the upper limits  $\mathcal{R}_{90\%}$  at 90% con-  
 258 fidence on the rate of eccentric binary coalescences per  
 259 unit volume. Following [51], and assuming an isotropic  
 260 and uniform distribution of sources,  $\mathcal{R}_{90\%}$  is given by

$$\mathcal{R}_{90\%} = \frac{2.3}{4\pi T \int_0^{r_{\text{max}}} dr r^2 \epsilon(r)}, \quad (2)$$

261 where  $\epsilon(r)$  is the detection efficiency as a function of dis-

FIG. 3. Upper limits at 90% confidence level on the rate of eccentric compact binary coalescences as a function of the distance. Only the best result is shown for each waveform. The inset shows the ratio of the rates with respect to O2 results [23] for ECBC\_A to ECBC\_F (see Table II for parameters).

Waveform	$M_1 [M_{\odot}]$	$M_2 [M_{\odot}]$	$e$	$\mathcal{R}_{90\%} [\text{Gpc}^{-3}\text{yr}^{-1}]$
ECBC_A	1.4	1.4	0.2	$9.97 \times 10^2$
ECBC_B	1.4	1.4	0.4	$8.09 \times 10^2$
ECBC_C	1.4	1.4	0.6	$3.21 \times 10^3$
ECBC_D	3.0	3.0	0.2	$3.99 \times 10^2$
ECBC_E	3.0	3.0	0.4	$8.89 \times 10^2$
ECBC_F	3.0	3.0	0.6	$2.43 \times 10^3$
ECBC_G	5.0	5.0	0.2	$1.50 \times 10^3$
ECBC_H	5.0	5.0	0.4	$5.10 \times 10^2$
ECBC_I	5.0	5.0	0.6	$6.98 \times 10^2$

TABLE II. Rate upper limits per unit volume at 90% confidence level on eccentric compact binary coalescences with various masses and eccentricity  $e$ , computed with equation 2.

262 tance, computed as the fraction of transients detectable  
 263 at a given distance [51],  $r_{\text{max}}$  is the maximum detectable  
 264 distance, and  $T = 204.4$  days is the total observing time.  
 265 For 1.4 – 1.4 solar masses eccentric binaries, rate upper  
 266 limits are  $\sim 1.5 - 2$  lower than the ones computed in  
 267 [52] for O2 data. Such improvement can be explained  
 268 by both the increased sensitivity of the search and the  
 269 increased livetime between O2 and O3. For compari-  
 270 son, estimated merger rates from the second LIGO-Virgo  
 271 GW transient catalogue [53] are  $23.9_{-8.6}^{+14.3} \text{Gpc}^{-3}\text{yr}^{-1}$  and  
 272  $340_{-240}^{+490} \text{Gpc}^{-3}\text{yr}^{-1}$  for binary black holes and binary  
 273 neutron stars respectively. With eccentric systems ex-  
 274 pected to be only a small fraction of the total binary  
 275 systems, the upper limits derived are compatible with an  
 276 absence of detection of such systems in this search; for  
 277 this reason, we do not constrain the fraction of eccen-  
 278 tric binary systems, but this may become possible in the  
 279 future with more sensitive detector data.

It is expected that continued improvements both to the gravitational-wave detectors and to the search algorithms, e.g. [49, 54, 55], will lead to either detections or improved limits on this portion of parameter space. Going forward, increasing the parameter space searched, such as for longer signals, is a high priority; these signals may include long-lived remnants of binary neutron star mergers, whose detection in gravitational waves may constrain the nature of the remnant [12, 25]. In addition, integration of Advanced Virgo into the analyses will be important, especially in case of a genuine signal for characterization. With range improvements of  $\sim 50\%$  expected for the fourth observing run and more than a factor of 2 expected by the fifth observing run [28], significant gains in detection possibilities can be expected.

 1027 <sup>264</sup> *Museo Storico della Fisica e Centro Studi e Ricerche “Enrico Fermi”, I-00184 Roma, Italy*  
 1028 <sup>265</sup> *Lancaster University, Lancaster LA1 4YW, United Kingdom*  
 1029 <sup>266</sup> *Università di Trento, Dipartimento di Matematica, I-38123 Povo, Trento, Italy*  
 1030 <sup>267</sup> *Indian Institute of Science Education and Research, Pune, Maharashtra 411008, India*  
 1031 <sup>268</sup> *Dipartimento di Fisica, Università degli Studi di Torino, I-10125 Torino, Italy*  
 1032 <sup>269</sup> *Indian Institute of Technology, Palaj, Gandhinagar, Gujarat 382355, India*  
 1033 <sup>270</sup> *Department of Physics, Kyoto University, Sakyou-ku, Kyoto City, Kyoto 606-8502, Japan*  
 1034 <sup>271</sup> *Department of Electronic Control Engineering, National Institute of Technology,*  
 1035 *Nagaoka College, Nagaoka City, Niigata 940-8532, Japan*  
 1036 <sup>272</sup> *Departamento de Matemática da Universidade de Aveiro and Centre for Research and*  
 1037 *Development in Mathematics and Applications, Campus de Santiago, 3810-183 Aveiro, Portugal*  
 1038 <sup>273</sup> *Marquette University, 11420 W. Clybourn St., Milwaukee, WI 53233, USA*  
 1039 <sup>274</sup> *Graduate School of Science and Engineering, Hosei University, Koganei City, Tokyo 184-8584, Japan*  
 1040 <sup>275</sup> *Faculty of Science, Toho University, Funabashi City, Chiba 274-8510, Japan*  
 1041 <sup>276</sup> *Faculty of Information Science and Technology,*  
 1042 *Osaka Institute of Technology, Hirakata City, Osaka 573-0196, Japan*  
 1043 <sup>277</sup> *Università di Firenze, Sesto Fiorentino I-50019, Italy*  
 1044 <sup>278</sup> *INAF, Osservatorio Astrofisico di Arcetri, Largo E. Fermi 5, I-50125 Firenze, Italy*  
 1045 <sup>279</sup> *Indian Institute of Technology Hyderabad, Sangareddy, Khandi, Telangana 502285, India*  
 1046 <sup>280</sup> *iTHEMS (Interdisciplinary Theoretical and Mathematical Sciences Program),*  
 1047 *The Institute of Physical and Chemical Research (RIKEN), Wako, Saitama 351-0198, Japan*  
 1048 <sup>281</sup> *INAF, Osservatorio di Astrofisica e Scienza dello Spazio, I-40129 Bologna, Italy*  
 1049 <sup>282</sup> *Department of Space and Astronautical Science,*  
 1050 *The Graduate University for Advanced Studies (SOKENDAI), Sagamihara City, Kanagawa 252-5210, Japan*  
 1051 <sup>283</sup> *Andrews University, Berrien Springs, MI 49104, USA*  
 1052 <sup>284</sup> *Research Center for Space Science, Advanced Research Laboratories,*  
 1053 *Tokyo City University, Setagaya, Tokyo 158-0082, Japan*  
 1054 <sup>285</sup> *Institute for Cosmic Ray Research (ICRR), Research Center for Cosmic Neutrinos (RCCN),*  
 1055 *The University of Tokyo, Kashiwa City, Chiba 277-8582, Japan*  
 1056 <sup>286</sup> *National Metrology Institute of Japan, National Institute of Advanced*  
 1057 *Industrial Science and Technology, Tsukuba City, Ibaraki 305-8568, Japan*  
 1058 <sup>287</sup> *Dipartimento di Scienze Aziendali - Management and Innovation Systems (DISA-MIS),*  
 1059 *Università di Salerno, I-84084 Fisciano, Salerno, Italy*  
 1060 <sup>288</sup> *Van Swinderen Institute for Particle Physics and Gravity,*  
 1061 *University of Groningen, Nijenborgh 4, 9747 AG Groningen, Netherlands*  
 1062 <sup>289</sup> *Faculty of Science, Department of Physics, The Chinese University of Hong Kong, Shatin, N.T., Hong Kong*  
 1063 <sup>290</sup> *Vrije Universiteit Brussel, Boulevard de la Plaine 2, 1050 Ixelles, Belgium*  
 1064 <sup>291</sup> *Department of Communications Engineering, National Defense*  
 1065 *Academy of Japan, Yokosuka City, Kanagawa 239-8686, Japan*  
 1066 <sup>292</sup> *Department of Physics, University of Florida, Gainesville, FL 32611, USA*  
 1067 <sup>293</sup> *Department of Information and Management Systems Engineering,*  
 1068 *Nagaoka University of Technology, Nagaoka City, Niigata 940-2188, Japan*  
 1069 <sup>294</sup> *Vrije Universiteit Amsterdam, 1081 HV Amsterdam, Netherlands*  
 1070 <sup>295</sup> *Department of Physics and Astronomy, Sejong University, Gwangjin-gu, Seoul 143-747, Korea*  
 1071 <sup>296</sup> *Department of Electrophysics, National Chiao Tung University, Hsinchu, Taiwan*  
 1072 <sup>297</sup> *Department of Physics, Rikkyo University, Toshima-ku, Tokyo 171-8501, Japan*  
 1073 (compiled October 1, 2021)

---

<sup>a</sup> Deceased, August 2020.
