Short title: Novel gellan gum hydrogel-bioactive glass injectable composites

Abstract

Mineralization of hydrogel biomaterials is desirable to improve their suitability as materials for bone regeneration. In this study, gellan gum (GG) hydrogels were formed by simple mixing of GG solution with bioactive glass microparticles of 45S5 composition, leading to hydrogel formation by ion release from the amorphous bioactive glass microparticles. This resulted in novel injectable, self-gelling composites of GG hydrogels containing 20% bioactive glass. Gelation occurred within 20 minutes. Composites containing the standard 45S5 bioactive glass preparation were markedly less stiff. X-ray μ CT proved to be a highly sensitive technique capable of detecting microparticles of diameter approximately 8 μ m, i.e. individual microparticles, and accurately visualizing the size distribution of bioactive glass microparticles and their aggregates, and their distribution in GG hydrogels. The widely used melt-derived 45S5 preparation served as a standard and was compared to a calcium-rich, sol-gel derived preparation (A2), as well as A2 enriched with zinc (A2Zn5) and strontium (A2Sr5). A2, A2Zn and A2Sr bioactive glass particles were more homogeneously dispersed in GG hydrogels than 45S5. Composites containing all four bioactive glass preparations exhibited antibacterial activity against methicillin-resistant *Staphylococcus aureus* (MRSA). Composites containing A2Zn5 and A2Sr5 bioactive glasses supported the adhesion and growth of osteoblast-like cells and were considerably more cytocompatible than 45S5. All composites underwent mineralization with calcium-deficient hydroxyapatite (CDHA) upon

1
2
3 incubation in simulated body fluid (SBF). The extent of mineralization appeared to be greatest
4
5 for composites containing A2Zn5 and 45S5. The results underline the importance of the
6
7 choice of bioactive glass when preparing injectable, self-gelling composites.

1. Introduction

Gellan gum (GG) is an inexpensive anionic polysaccharide produced biotechnologically using bacteria, from which hydrogels can be formed by crosslinking with divalent ions such as Ca^{2+} .

In order to improve the suitability of hydrogels for applications in bone regeneration, various strategies have been employed to enrich hydrogels with a mineral phase (Gkioni et al., 2010), most commonly a form of calcium phosphate (CaP) which is desirable to promote bioactivity, i.e. a material's capability to bond directly to bone tissue (LeGeros, 1991). The presence of CaP also promotes adhesion and proliferation of bone-forming cells *in vitro* and reinforces the hydrogel mechanically (Douglas et al., 2014a).

The most common strategy to incorporate minerals is the addition of preformed inorganic particles. Several groups have incorporated microparticles of bioactive glass, (BG), especially the 45S5 formulation (composition in wt%: 45 SiO_2 , 24.5 CaO , 24.5 Na_2O , and 6 P_2O_5) (Hench, 1998), into hydrogels, and subsequently incubated the resulting composites in simulated body fluid (SBF) to induce CaP formation (Marelli et al., 2010). Upon incubation in SBF, an apatite forms on the surface of bioactive glasses, resulting in bioactivity (Jones, 2013).

A further advantage of using bioactive glasses is their high amorphousness and ability to release Ca^{2+} to crosslink GG and induce GG hydrogel formation (Douglas et al., 2014b, Gorodzha et al., 2016). Such composites can be implanted in a minimally-invasive fashion by injection.

Other advantages of bioactive glasses include their antibacterial properties, both alone and as components of hydrogel-bioactive glass composites (Allan et al., 2001, Douglas et al., 2014b,

1
2
3 Gubler et al., 2008, Hu et al., 2009) and, since bioactive glasses are amorphous in nature,
4 straightforward incorporation of metal ions and therapeutic drugs. These can influence cell
5 behavior and impart antibacterial activity (Hoppe et al., 2011, Hum and Boccaccini, 2012).
6
7
8
9

10
11 Two such metal ions relevant in bone regeneration have been incorporated into bioactive
12 glasses: zinc (Zn) and strontium (Sr). Previously, it was revealed that inorganic biomaterials
13 enriched with Zn demonstrate antibacterial properties (Douglas et al., 2015), while Sr-
14 enriched inorganic biomaterials have been reported to promote osteoblast proliferation and
15 differentiation (Boanini et al., 2012).

21
22
23

24
25 The aim of the present study was the generation of novel, self-gelling, injectable hydrogel-
26 bioactive glass composites by simple addition of bioactive glass microparticles to GG
27 solution, resulting in hydrogel formation. The bioactive glass type studied was a Ca-rich
28 preparation derived by a sol-gel process, hereafter referred to as A2. In previous work, A2
29 was enriched with Sr, and incorporated into solid polymer scaffolds, leading to improved cell
30 proliferation (Dziadek et al., 2016). In the present study, A2 was enriched either with Sr or
31 with Zn to create novel compositions, hereafter referred to as A2Sr5 and A2Zn5, respectively.

It was hypothesized that the composition of the bioactive glass preparation would influence:

- (i) the speed of gelation of the GG hydrogel to form the hydrogel-bioactive glass composite and the viscoelastic properties of the composite;
- (ii) the homogeneity of the distribution of the bioactive glass within the composite;
- (iii) the composites' antibacterial activity;
- (iv) the adhesion and proliferation of osteoblast-like cells seeded on the composites and

1

3 (v) the extent of mineral formation upon incubation of the composites in simulated body fluid
4
5 (SBF).
6
7
8

9
10 Bioactive glass microparticles were characterized by laser diffraction. The speed of gelation
11 of hydrogel-bioactive glass composites and their viscoelastic properties were studied by
12 rheometry. X-ray micro-computed tomography (μ CT) analysis of composites was performed.
13
14 This advanced technique not only enables the distribution of bioactive glass microparticles
15 and aggregates in hydrogels to be studied, but also evaluation of the sizes of aggregates. This
16 high-resolution technique is applicable in the wet state, unlike other high-resolution
17 techniques such as electron microscopy.

24
25
26

27 Biological characterization involved assessment of the cytocompatibility of the composites
28 and their ability to promote the adhesion and proliferation of osteoblast-like cells, as well as
29 their antibacterial properties towards methicillin-resistant *Staphylococcus aureus* (MRSA).
30
31

32
33
34 *Staphylococcus aureus* is the most commonly occurring in orthopedic healthcare-related
35 infections. MRSA is particularly problematic due to its resistance to certain antibiotics. It is
36 desirable that a material for bone regeneration exhibits antibacterial activity as a preventative
37 measure to combat bone infection, or osteomyelitis. MRSA are known to commonly appear
38 on skin but can cause infections in bone defect sites and broken bones, especially if the
39 patient's immune system is weakened. MRSA can spread to bones by invading a severe
40 injury, deep cut, or wound near to a bone defect, or by entering at another site and migrating
41 to the bone defect via the blood stream.

8 9 10 **2. Materials and Methods**

11 12 13 14 *2.1 Materials*

15
16 All materials, including GG (Gelzan™ CM, Product no. G1910, “Low-Acyl”, molecular
17
18 weight 200-300 kD), were obtained from Sigma-Aldrich, unless stated otherwise.
19
20

21 22 23 *2.2 Bioactive glass particle synthesis and characterization*

24 25 *2.2.1 Bioactive glass synthesis*

26
27 The A2, A2Sr5, and A2Zn5 bioactive glasses were produced by a sol-gel method as
28
29 described previously (Laczka et al., 2000). Chemical compositions of obtained bioactive
30
31 glasses are presented in Table 1. Tetraethyl orthosilicate (TEOS, $\text{Si}(\text{OC}_2\text{H}_5)_4$), triethyl
32
33 phosphate (TEP, $\text{OP}(\text{OC}_2\text{H}_5)_3$), calcium nitrate tetrahydrate ($\text{Ca}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$), strontium
34
35 nitrate ($\text{Sr}(\text{NO}_3)_2$), and zinc nitrate ($\text{Zn}(\text{NO}_3)_2$) (POCh, Poland), were used as the starting
36
37 materials. Ethanol (96%; POCh, Poland) was used as a solvent and HCl solution (POCH,
38
39 Poland) was applied as a catalyst of the hydrolysis and polycondensation reactions. Obtained
40
41 solutions were left at the ambient conditions until gels were formed. After drying at 80 °C,
42
43 gels were heated up to 700 °C and kept at this temperature for 20 h. The gel-derived materials
44
45 were then milled and sieved to obtain grain size < 45 μm
46
47

48
49 Melt-derived standard bioactive glass powder of composition 45S5 was obtained from the
50
51 company Schott AG, Germany. This glass is fabricated by a melting technique which results,
52
53 after milling, in dense microparticles of irregular shape. The same bioactive glass powder has
54
55
56
57
58
59
60

1
2
3 been used previously in several studies combined with biopolymers, for example to prepare
4
5 bioactive glass-soy protein composites (Silva et al., 2014).
6

7 2.2.2 Zeta potential measurements

8
9 A2Zn5, A2Sr5 and 45S5 bioactive glass particles were suspended in Phosphate Buffered
10
11 Saline (PBS, prepared in lab) and distilled H₂O at a concentration 1 mg/ml, for zeta potential
12
13 measurements. Zeta potential was measured using a Zetasizer Nano Series (Malvern
14
15 Instruments, Hoeilaart, Belgium). The microparticle suspensions were transferred into DTS
16
17 1060 disposable folded capillary cells. Measurements were carried out at a temperature of
18
19 25°C. Because of possible reaction of bioactive glass with dispersant agent (H₂O, PBS) for
20
21 each as prepared suspension the pH was also measured due to its impact on the zeta potential.
22
23 For bioactive glass-water suspensions, pH was adjusted to pH 7.5 with 1 M HCl.
24
25

26
27 The potential was determined five times (each measurement being the average of 100 runs)
28
29 and the mean values and standard deviations were calculated (see table). The instrument
30
31 automatically calculates zeta potential according to Smoluchowski's equation.
32
33

34 2.2.3 Microparticle size distribution measurements

35
36 Microparticle size distributions were measured by laser diffraction (Mastersizer-S long bench,
37
38 Malvern Instruments, Malvern, UK), using the wet dispersion technique. The powder (about
39
40 100 mg) was dispersed in 10 ml of a 0.1% (m/v) aqueous polysorbate 80 solution. The
41
42 resulting suspension was added to the MS1 Small Volume Dispersion unit (Malvern
43
44 Instruments, Malvern, UK) in order to obtain an obscuration of the laser beam of
45
46 approximately 20%. The microparticle size distribution was measured using the following
47
48 parameters: 300RF lens, 2.4 mm active beam length, 1500 rpm stirrer speed, 6000 scans,
49
50 polydisperse analysis model.
51
52
53
54
55
56
57
58
59
60

2.3 *Production of hydrogel-bioactive glass composites, rheometry and ion release studies using ICP-OES*

Briefly, 1 ml pre-autoclaved (121°C for 15 minutes) aqueous 0.875% (w/v) GG solution was mixed with 200 mg pre-autoclaved bioactive glass particles at room temperature and shaken vigorously to yield 20% (w/v) GG-bioactive glass composites. To make bioactive glass-free composites as control samples, 800 µl GG solution and 200 µl pre-sterilized 0.15% (w/v) CaCl₂ solution were heated to 70°C, mixed and allowed to cool and set at room temperature. Gelation speed was investigated by performing rheometrical measurements with an AR1000N Rheometer (TA Instruments). All experiments were performed at 37° C at strain 1% and frequency 1 Hz using a plate-cone setup with a stainless steel plate and an acrylic cone of 4 cm diameter.

To study release of ions from composites, composites of volume 1 ml were submerged in 1 ml ddH₂O water for 24 h. The water was retained and analyzed using ICP-OES as described previously (Douglas et al., 2012). Samples were directly diluted 1:10 with 0.14 M HNO₃ prepared after properly diluting 14 M HNO₃ (purchased from Fisher Chemicals, UK, and further purified by sub-boiling distillation in a PFA system) with ultrapure water obtained from an Element Milli-Q water purification system (Merck Millipore, USA). External calibration was performed by measuring multi-element standards of Ca, Na, Zn, Sr and P at different concentration levels (0, 0.05, 0.1, 0.5, 1, 2.5 and 10 mg L⁻¹), prepared by properly diluting the corresponding single element standard solutions (of 1 g L⁻¹) with 0.14 M HNO₃. Y was added in all samples and calibration standards in a concentration of 1 mg L⁻¹ to be used as internal standard to correct for matrix effects and/or possible instrument instability. Elemental quantification measurements were performed in a Spectro Arcos ICP-OES instrument. 3 replicates were performed per sample. Method limits of detection were

calculated as 3 times the standard deviation of the blanks (n=20) divided by the slope of the calibration curve and multiplied by the sample dilution factor (10).

2.4 Three-dimensional X-ray imaging

Image acquisition was performed with a laboratory x-ray source at the Detector Lab of the Institute for Photon Science and Synchrotron Radiation at the Karlsruhe Institute of Technology, Karlsruhe, Germany. For x-ray tomography acquisitions, an X-ray tube (Viscom X9160-D ED) was set to 60 kV voltage and 120 μ A current. For detection, a Dexela 1207 with a 150 μ m CsI CMOS sensor with active pixel size of 74.8 μ m was used.

To ensure focal spot limited spatial resolution, the source sample distance and source detector distance were adjusted to 3.5 cm and 70.0 cm respectively with a total magnification of 20x resulting in a pixel size of 3.7 μ m and a field of view of 3.2 \times 5.7 mm².

For each measurement, a series of 1200 projection images were taken over a 360° angular range with an exposure time of 4 s.

GG hydrogel-bioactive glass composites containing A2, A2Sr, A2Zn and 45S5 particles were placed in plastic Eppendorf tubes and visualized by means of x-ray μ CT .

The 3-D volumes were reconstructed with Octopus software. To quantitatively study bioactive glass agglomerates, the Otsu thresholding method was used with subsequent labelling of connected components in a 3D volume performed with the morphology module of open source Python library (SciPy) (Jones et al., 2001). Rendering and visualization of segmented bioglass agglomerations in 3D was performed by means of Avizo 8.1 software.

2.5 Antibacterial testing

To evaluate antibacterial properties, composites of volume 1 ml were submerged with a silicone disc in 1 ml containing 10⁴ CFU Methicillin-resistant *Staphylococcus aureus*

1
2
3 (MRSA) Mu50 in Müller-Hinton broth. The disc served as a substrate for MRSA attachment
4 and growth. After 24 h incubation at 37°C, samples were removed, medium was removed and
5 discs were washed with physiological saline to remove non-adhered bacteria. Discs were
6 collected and the number of CFU per silicone discs was determined by plating. Silicone discs
7 without added composites served as a control. For all sample groups, n = 3. Statistical
8 analysis was performed using a Kruskal-Wallis test and SPSS software. A value of $p \leq 0.05$
9 was considered significant.

21 2.6 Characterization of osteoblast-like cell attachment and growth

22 2.6.1 Cell culture on GG-bioactive glass composites

23
24
25
26 Hydrogel composites were cast under sterile conditions in wells of 12-well cell culture plates
27 (TPP, Switzerland), 1 ml per well. Six-mm discs were cut out using a sterile hole punch and
28 were used for cell culture experiments. For cell adhesion and growth analysis, human
29 osteoblast-like MG-63 cells (European Collection of Cell Cultures, Salisbury, UK; Cat. No.
30 86051601) were used. [These cells are considered as a suitable model for studies on cell](#)
31 [adhesion and proliferation and have been widely used for testing biocompatibility of various](#)
32 [biomaterials \(Douglas et al., 2014b, Jirka et al., 2013, Vandrovcova et al., 2014\).](#) Each GG-
33 bioactive glass composite was placed in a well of a 24-well plate and a suspension of 100000
34 cells in 1.5 ml cell culture medium, i.e. GlutaMax High Glucose DMEM containing 10% fetal
35 bovine serum, 0.1 mM Sodium Pyruvate and 1% Penicilin-Streptomycin, (all Gibco,
36 Invitrogen), was added.
37

45
46
47
48
49

50 2.6.2 Cell visualization

51
52 A LIVE/DEAD staining (Calcein AM/propidium iodide, Life Technologies) was performed to
53 evaluate cell adhesion and growth. After rinsing with PBS, the supernatant was replaced by 1
54 ml PBS solution supplemented with 2 μ l (1 mg/ml) calcein AM and 2 μ l (1 mg/ml) propidium
55
56
57
58
59
60

1
2
3 iodide. Cultures were incubated for 30 minutes at room temperature, washed twice with PBS
4
5 solution and evaluated by fluorescence microscopy (IX 51 epifluorescence microscope
6
7 equipped with a DP 70 digital camera; both manufactured by Olympus, Japan). Evaluations
8
9 were performed on day 3 and 7 post-seeding.
10

11 *2.6.3 Metabolic test*

12
13 Metabolic activity of the cells was evaluated to estimate the growth (number) of the cells on
14
15 day 7 after seeding. Triplicates of samples were analyzed. The samples were replaced into
16
17 fresh wells in 24-well plate and washed with PBS. The composite discs were then incubated
18
19 in resazurin solution (Alamar blue, Sigma, 40 μ M work solution) diluted in cell culture
20
21 medium without phenol red (DMEM with low glucose, without phenol red; Sigma, USA, Cat.
22
23 No. D2902). After 4 hour incubation in cell culture incubator, the composites were placed
24
25 back into their cell culture medium. Resazurin fluorescence was measured at 590 nm with
26
27 excitation at 530 nm.
28
29
30

31 *2.6.4 Testing of eluates from composites*

32
33 To produce eluates, composites of volume 1 ml were dissected into 4 equal parts. Each part
34
35 was incubated in 5 ml of cell culture medium at 37 °C for 48 h. Eluates were diluted in cell
36
37 culture medium by factors of 1 (undiluted), 2, 4, and 8. MG-63 cells (10000 per well of a 96-
38
39 well plate) were subsequently incubated in eluate at the aforementioned dilutions for 72 h.
40
41 Afterwards, the eluate was replaced by 0.2 ml resazurin work solution and the metabolic test
42
43 was followed as described above. Triplicate measurements were performed. The viability was
44
45 calculated as a percentage of control cultures incubated with cell culture medium without
46
47 eluate.
48
49
50

51 *2.6.5 Statistical Analysis*

52
53 The quantitative results were presented as the mean \pm SD (standard deviation). The statistical
54
55 analyses were performed using SigmaStat (Jandel Corporation, San Jose, CA USA). Multiple
56
57
58
59
60

1
2
3 comparison procedures were carried out by one way ANOVA. The multiple comparisons
4
5 were counted by the All Pairwise Multiple Comparison Procedure (Bonferroni t-test);
6
7 multiple comparisons versus control were counted by the Dunnett test. A value of $p \leq 0.05$
8
9 was considered significant.
10

11 12 13 14 *2.7 Mineralization studies in SBF*

15 16 *2.7.1 SBF production and sample incubation*

17
18 The mineralization process of hydrogel-bioactive glass composites was performed by
19
20 incubation in simulated body fluid (SBF) prepared according to Kokubo (Kokubo et al.,
21
22 1990). The composites were immersed in SBF solution and incubated at 37 °C in separate
23
24 containers for 28 days. The ratio of the composite's weight (g) and solution's volume (ml)
25
26 was close 1/100. Afterwards the composites were taken out of SBF, frozen at -24 °C and
27
28 subsequently subjected to a lyophilization process in order to obtain dry mass. Freeze-drying
29
30 was performed using Labconco FreeZone 6l for 48 hours.
31
32

33 34 35 36 *2.7.2 Physicochemical and morphological characterization of freeze-dried samples post-* 37 38 *incubation: FTIR, SEM, ICP-OES*

39
40 Prior to FTIR, SEM and ICP-OES analysis, samples were freeze-dried.

41
42 Before and after mineralization experiments and subsequent lyophilization, the structure of
43
44 the hydrogels was examined using FTIR. Spectra were recorded with a Bruker Company
45
46 Vertex 70v spectrometer [using the KBr technique](#). Spectra were collected in the range 4000–
47
48 [400](#) cm^{-1} and 128 scans were accumulated at 4 cm^{-1} resolution.
49

50
51 Morphology and elemental analysis of all freeze-dried samples before and after mineralization
52
53 in SBF were determined using SEM (Nova NanoSEM 200 FEI Europe Company, USA,
54
55 accelerating voltage 15 kV) coupled with an energy dispersion X-ray (EDX) analyzer. The
56
57
58
59
60

EDX spectra were collected at the point indicated by arrow in SEM image. Materials were analyzed after coating with a thin conductive carbon layer.

Elemental composition of samples was determined using ICP-OES as described previously (Douglas et al., 2012). The ICP-OES technique, with detection limit between 1 $\mu\text{g}/\text{dm}^3$ and 1000 g/dm^3 , was also used to investigate the changes in ion concentration in the SBF after 14 and 28 days of composite incubation.

3. Results

3.1 Bioactive glass microparticle characterization, formation of hydrogel-bioactive glass composites and ion release from composites

Laser diffraction analysis results are shown in Figure S1a. A2, A2Zn and A2Sr preparations displayed similar size distributions, with $D[v,0.5]$ values of 17.3, 15.5 and 28.9 μm , respectively. $D[v,0.5]$ and $D[v,0.9]$ defines the diameter (based on the volume distribution of the particles) at which 50 and 90% of the particles are smaller than this diameter. Microparticles in the 45S5 preparation were markedly smaller, $D[v,0.5]$ and $D[v,0.9]$ values of 2.9 and 6.2 μm , respectively.

Sterilization by autoclaving had no effect on laser diffraction results (data not shown).

Zeta potential measurements are displayed in Table 2. In ddH₂O, the strongest alkalization was observed for A2. A2 showed the most neutral zeta potential in ddH₂O, while values for A2Zn and A2Sr were more negative by approximately 11 mV. The value for 45S5 was more negative still, approximately 43 mV more negative than for A2. In ddH₂O with pH fixed at 7.5, the most negative zeta potential was exhibited 45S5 (approximately -23 mV) followed by A2 (approximately -8 mV). A2Zn was marginally more neutral, while A2Sr was markedly more neutral (approximately -2 mV). In PBS, alkalization was less extreme than in ddH₂O.

1
2
3 The strongest alkalization was observed for A2. Zeta potential values between -17 and -19
4 mV for A2 and A2Sr5, while values for A2Zn5 were more negative (approximately -25 mV)
5
6 and values for 45S5 were more negative still (approximately -29 mV).
7
8

9
10 Results of rheometrical analysis are displayed in Figure S1b. In all cases, gelation appeared to
11
12 have reached a plateau value after 20 minutes. Composites containing 45S5 exhibited
13
14 markedly lower storage modulus values, suggesting lower stiffness.
15

16 ICP-OES release of ions after 24 h (Table 3) revealed that the concentration of Zn released
17 from composites containing A2Zn5 was $0.16 \pm 0.18 \text{ mg dm}^{-3}$. Sr release from composites
18 containing A2Sr5 was considerably higher (concentration $34.04 \pm 10.46 \text{ mg dm}^{-3}$). All
19 composites released Ca. Release of P was negligible from all composites except those
20 containing 45S5. Release of Na from composites containing 45S5 was two orders of
21 magnitude higher than that from other composites.
22
23
24
25
26
27
28
29
30
31

32 *3.2 X-ray μ CT examination*

33
34 Transversal sections of hydrogel-bioactive glass composites at two different heights are
35
36 shown in Figure 1a. It can be seen that the distribution of bioactive glass in the composite
37
38 containing 45S5 was significantly less homogeneous. The most homogeneous distribution of
39
40 visible microparticles/microparticle aggregates was observed in the composite containing
41
42 A2Zn. This was confirmed by imaging of 3D composites distribution, the results of which are
43
44 shown in Figure 1b.
45

46
47 Results of the analysis of the size distribution of the bioactive glass microparticles and
48
49 microparticle aggregates in composites containing A2, A2Zn, A2Sr and 45S5 are presented in
50
51 Figures 2, S2, S3, S4 and S5, respectively. A significantly lower number of
52
53 microparticles/microparticle aggregates was observed in composites containing 45S5 (Figure
54
55 2a). Furthermore, the percentage of all microparticles/microparticle aggregates in the smallest
56
57
58
59
60

1
2
3 size range ($320-1000 \mu\text{m}^3$) was the lowest. Regarding the detailed size distribution of
4
5 microparticles/microparticle aggregates (Figures S2, S3, S4, S5), in region I, encompassing
6
7 microparticle/microparticle aggregate volumes in the range $0-10^4 \mu\text{m}^3$, the highest number of
8
9 microparticles/microparticle aggregates was observed for the composite containing A2Sr
10
11 (approximately 110000). Values for composites containing A2 and A2Zn were markedly
12
13 lower (approximately 50000), while the value for the composite containing 45S5 was
14
15 markedly lower still (approximately 25000). In region II, encompassing
16
17 microparticle/microparticle aggregate volumes in the range $10^4-10^5 \mu\text{m}^3$, the highest values
18
19 were observed for the composite containing A2Sr, approximately twice as high as the values
20
21 for composites containing A2 and A2Zn. The values for the composite containing 45S5 were
22
23 approximately one order of magnitude lower. The same trend was observed in regions III
24
25 ($10^5-10^6 \mu\text{m}^3$) and IV ($10^6-10^7 \mu\text{m}^3$).

3.3 Cell biological characterization with MG-63 osteoblast-like cells

32
33
34 Fluorescence microscopy images of MG-63 osteoblast-like cells cultured directly on
35
36 hydrogel-bioactive glass composites and in their eluates are presented in Figure 3a. On
37
38 composites containing A2, A2Zn and A2Sr, cells remained viable after 3 days, formed viable
39
40 clusters after 7 days, and in the case of composites containing A2, cell layers were formed.
41
42 However, no viable cells were observed on composites containing 45S5 after 3 days or 7
43
44 days. Cells proliferating on the bottom of the same wells together with composites containing
45
46 A2, A2Zn and A2Sr formed layers of viable cells with no dead cells after 7 days. However,
47
48 no viable cells and some dead cells were observed in cells cultured together with composites
49
50 containing 45S5. It was noted that cell culture medium in the presence of composites
51
52 containing 45S5 was noticeably more purple-colored, suggesting greater alkalization of the
53
54 medium.
55
56
57
58
59
60

1
2
3 Cell numbers on composites assessed by metabolic test are displayed in Figure 3b. Cell
4 numbers were significantly higher on composites containing A2, A2Zn and A2Sr than on
5 those containing 45S5. Furthermore, values for composites A2Zn were significantly higher
6 than those for composites containing A2Sr.
7
8

9
10
11 Cell numbers after cultivation in eluates from composites are shown in Figure 3c. Cell
12 proliferation in undiluted eluates was significantly lower, especially for composites containing
13 A2 and 45S5. Values for eluates diluted by a factor of 2 were closer to control values, but still
14 significantly worse for all composites except those containing A2Sr. Cell numbers were not
15 lower than controls when eluates were diluted by factors of 4 or 8.
16
17
18
19
20
21
22
23
24

25 *3.4 Antibacterial testing*

26
27 The results of antibacterial testing are displayed in Figure 3d. All composites containing
28 bioactive glass showed significantly greater antibacterial activity than bioactive glass-free GG
29 hydrogel controls. The values for composites containing 45S5 were markedly lower than
30 those for the composites containing A2, A2Zn and A2Sr.
31
32
33
34
35
36
37

38 *3.5 Mineralization of composites in SBF*

39
40 FTIR spectra of hydrogel-bioglass composites before and after 28 days of incubation in SBF
41 are shown in Figure 4. Incubation in SBF resulted in some changes. The bands at 565 and 605
42 cm^{-1} , corresponding to ν^4 antisymmetric bending of PO_4^{3-} groups became more visible, and
43 the band in the range of 1055-1090 cm^{-1} , corresponding to ν^4 antisymmetric stretching of
44 PO_4^{3-} groups became more intense and narrower (Koutsopoulos, 2002). Furthermore, the
45 increase in intensity of the band at about 870 cm^{-1} , which could be connected with
46 superimposed symmetric stretching mode of the P–O(H) bond of the HPO_4^{2-} group and C – O
47 vibrations in CO_3^{2-} groups appearing in the structure of calcium phosphate, was observed
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 (Koutsopoulos, 2002, Rosseeva et al., 2008). Additionally, a new shoulder at 1220 cm^{-1} and
4
5 new band of low intensity at 800 cm^{-1} appeared, which may be due to silica groups in the
6
7 CaP/silica gel layer). The appearance of the aforementioned bands points to the formation of
8
9 carbonated calcium phosphate (CaP) in the composites upon immersion in SBF. Further
10
11 indirect evidence is provided by the disappearance or attenuation of bands characteristic for
12
13 GG at 700 cm^{-1} and 1430 cm^{-1}
14
15

16
17 SEM images and EDX spectra of hydrogel-bioactive glass composites before and after 28-day
18
19 incubation in SBF are shown in Figure 5. In the case of pure GG, no visible morphological
20
21 changes after immersion in SBF were observed. Elemental analysis revealed the presence of
22
23 Na and Cl on the surface of material. Composites showed morphological changes
24
25 characteristic for precipitation of calcium phosphate, namely the appearance of roughly
26
27 spherical, “cauliflower-like” deposits rich in P and Ca.
28
29

30
31 Results of elemental analysis by ICP-OES after incubation of hydrogel-bioactive glass
32
33 composites for 28 days in SBF are shown in Table 4. As expected, no Ca or P was detected in
34
35 GG controls without bioactive glass. Composites containing A2, A2Zn and A2Sr contained
36
37 similar masses of Ca and P. In contrast, the masses of Ca and P in composites containing
38
39 45S5 were markedly lower. By comparing the molar amounts of elements present after
40
41 incubation in SBF with the theoretical molar amounts present before incubation in SBF, it can
42
43 be seen that the % molar increase in Ca was highest for composites containing 45S5, probably
44
45 due to the much greater alkalization which favors HA crystallization. Composites containing
46
47 A2Zn exhibited markedly higher % molar increases in Ca and P than composites containing
48
49 A2 and A2Sr, but not 45S5. Approximately 48% and 80% of initial molar amounts of Zn and
50
51 Sr, respectively, were lost due to incubation.
52
53
54
55

56 Ion concentration in SBF after immersion of hydrogel-bioactive glass composites are
57 presented in Table 5. After 14 days of incubation, hydrogel containing A2, A2Zn and A2Sr
58
59
60

1
2
3 glasses showed much higher concentration of Ca in SBF, compared to composites containing
4 45S5. In all cases, decreases in Ca concentration were observed after 28 days. This correlates
5 with the gradual reduction of P concentration with increasing incubation time, indicating CaP
6 formation. ICP-OES analysis of SBF showed small changes in Na concentration for
7 composites containing A2, A2Zn5 and A2Sr5, while composites containing 45S5 revealed
8 significant solubility of Na⁺ ions. Concentrations of Sr and Zn in SBF determined by ICP-
9 OES analysis (Table 5) confirmed the results of elemental composition of composites (Table
10 4), indicating lower Zn ion release compared to Sr, which was also indicated during
11 composite incubation in ddH₂O for 24 h (Table 3).

4. Discussion

31 As stated in the introduction, it was hypothesized that the composition of the bioactive glass
32 preparation would influence: (i) the speed of gelation of the GG hydrogel to form the
33 hydrogel-bioactive glass composite and the viscoelastic properties of the composite; (ii) the
34 homogeneity of the distribution of the bioactive glass within the composite; (iii) the
35 composites' antibacterial activity; (iv) the adhesion and proliferation of osteoblast-like cells
36 seeded on the composite and (v) the extent of mineral formation upon incubation of the
37 composites in simulated body fluid (SBF).
38
39
40
41
42
43
44
45
46
47

48 Composites containing 45S5 were mechanically weaker (Figure S1b). This can be attributed
49 to lower Ca²⁺ ion release from the preparation, which would result in lower ionic crosslinking
50 of GG. 45S5 is melt-derived, while A2, A2Zn and A2Sr are all sol-gel derived. It is well
51 known that, in general, sol-gel derived bioactive glasses release more ions than melt-derived
52 bioactive glasses. Additionally 45S5 bioactive glass releases also Na⁺ ions which do not
53
54
55
56
57
58
59
60

1
2
3 crosslink [as strongly as divalent ions \(Morris et al., 2012\)](#). Furthermore, the distribution of the
4
5 45S5 preparation was markedly less homogeneous. This could be seen visually using X-ray
6
7 μ CT imaging (Figure 1). Furthermore, analysis of bioactive glass microparticles/microparticle
8
9 aggregates revealed a lower total number of microparticles/aggregates (Figure 2a) and a lower
10
11 percentage of microparticles/microparticle aggregates in the lowest size category (Figure 2b),
12
13 which indicate a larger degree of aggregation. It is noteworthy that the 45S5 preparation
14
15 exhibited the lowest particle size (Figure 1a) but the least homogeneous distribution (Figure
16
17 1). This can be assigned to a lower stability and tendency for aggregation of small particles.
18
19 More neutral zeta potential is certainly not the cause, since the 45S5 preparation displayed
20
21 markedly more negative values (Table 2).
22
23
24
25
26

27
28 In this study, bioactive glass microparticles/microparticle aggregates of volumes as low as
29
30 $320 \mu\text{m}^3$ could be detected and quantified (Figure 2b). This volume corresponds to an
31
32 equivalent microparticle diameter of $8.5 \mu\text{m}$ (assuming a spherical microparticle shape). This
33
34 is approximately one order of magnitude higher than the resolution obtained in our previous
35
36 work on synchrotron X-ray μ CT analysis of microparticles (Gorodzha et al., 2016).
37
38 Considering the microparticle diameters calculated by laser diffraction (Figure S1a), it
39
40 appears that a high proportion of individual bioactive glass microparticles can be detected by
41
42 the X-ray μ CT technique applied in this study. It is known that aggregation of inorganic
43
44 particles in hydrogels and inhomogeneous distribution are common occurrences
45
46 (Leeuwenburgh et al., 2010, Leeuwenburgh et al., 2007). The high-resolution technique
47
48 presented in this study offers the possibility of semi-quantitative or even quantitative
49
50 evaluation of microparticle dispersion and aggregation in hydrogel biomaterials. This should
51
52 be useful for evaluating strategies to reduce microparticle aggregation and improve
53
54 dispersion.
55
56
57
58
59
60

1
2
3
4
5 The poorer cell proliferation on composites containing 45S5 and in the eluates from these
6 composites might be ascribed to increased alkalization of the medium due to Na^+ ions release
7 as was confirmed by ICP-OES analysis of SBF (Figure 3a, 3b and 3c, Table 5). Another
8 possible explanation is a relatively low stiffness of these materials. It is known that the
9 adhesion and spreading of cells on soft and deformable materials is limited or even disabled,
10 because these materials cannot resist the tractional forces generated by cells (for a review, see
11 (Bacakova et al., 2011)). Similarly, the osteogenic differentiation of human umbilical cord
12 stem cells was lower on polyacrylamide gels of a lower stiffness (Witkowska-Zimny et al.,
13 2012). In addition, the composites containing 45S5 had a markedly more negative zeta
14 potential. In our earlier studies, negative zeta potential was associated with a lower
15 proliferation of human osteoblast-like MG-63 and Saos-2 cells (Jirka et al., 2013,
16 Vandrovцова et al., 2014).

17
18
19
20
21
22
23
24
25
26
27
28
29
30
31
32 It is noteworthy that cells seeded on composites containing A2Zn and A2Sr did not proliferate
33 worse than those seeded on composites containing A2, which did not contain any Zn or Sr.
34 Hence, incorporation of Zn or Sr in bioactive glass does not adversely affect
35 cytocompatibility. Cells cultured directly on composites containing A2, A2Zn and A2Sr
36 displayed a round, spherical morphology after 1 day, but a more spread morphology after 7
37 days, suggesting better adhesion. It is possible that this improved morphology is due to
38 proteins secreted by the cells in the course of 7 days which adsorbed to the composite surface.
39
40
41
42
43
44
45
46
47
48

49
50 The antibacterial effect of composites containing A2 observed in this study (Figure 3d) is
51 consistent with results reported in previous work (Douglas et al., 2014b). Composites
52 containing A2Zn were not more antibacterial than those containing A2 or A2Sr, despite the
53 well-known antibacterial effect of Zn. It may be that insufficient amounts of Zn were released
54
55
56
57
58
59
60

1
2
3 from composites. ICP-OES analysis of SBF (Table 5) confirmed low solubility of Zn ions
4 from this material even in long-term incubation (up to 28 days). Furthermore, ICP-OES
5 analysis also revealed low Zn release into ddH₂O (Table 3). GG has been reported to have a
6 higher affinity for Zn²⁺ than Ca²⁺ (Verma et al., 2012), hence Zn²⁺ release may have been
7 impeded by the GG hydrogel network. The higher antibacterial activity of composites
8 containing 45S5 might be ascribed to an increase in pH of the bacterial culture medium;
9 however, this may not be the only factor. Indeed, increases in pH, high ion release (mainly
10 Na⁺, which is one of the main component in 45S5 glass; Na⁺ release in ddH₂O after 24 h was
11 approximately two orders of magnitude higher from composites containing 45S5 than from
12 other composites (Table 3)), ionic strength and bioactive glass debris production have all been
13 proposed to contribute to antibacterial effect of bioactive glasses in solution (Allan et al.,
14 2001, Gubler et al., 2008, Hu et al., 2009, Misra et al., 2010, Zehnder et al., 2006, Stoor et al.,
15 1998). The antibacterial effect of 45S5 in this study is consistent with the results obtained in
16 some studies (Hu et al., 2009, Misra et al., 2010, Rivadeneira et al., 2013), although it should
17 be noted that little or no antibacterial effect was demonstrated in other studies (Bellantone et
18 al., 2002, Gorriti et al., 2009, Xie et al., 2008). Further work should involve bacteria different
19 from *Staphylococcus aureus*.

20
21
22

25
26
27
28
29
30
31
32
33
34
35
36
37
38
39
40
41
42
43 Formation of CDHA in composites containing bioactive glasses after incubation in SBF was
44 confirmed directly by FTIR (Figure 4) and SEM/EDX (Figure 5) analysis, and indirectly by
45 the increase in Ca and P content measured using ICP-OES (Table 3). The reasons for the
46 higher relative increases in Ca and P in composites containing A2Zn and 45S5 remain
47 unclear. Nevertheless, it is known that some ceramic materials, e, g. hydroxyapatite and other
48 calcium phosphates, are able to trap actively Ca ions from the surrounding solutions, e.g. from
49 the cell culture medium, and this depletion of Ca attenuates the cell growth on these substrates
50
51
52
53
54
55
56
57
58
59
60

1
2
3 (Mestres et al., 2012, Schumacher et al., 2013). X-ray μ CT examination (Figures 1, 2, S2, S3,
4
5 S4, S5) did not reveal more homogeneous distribution of bioactive glass in these composites.
6
7 Nor was a greater number or proportion of small microparticles/aggregates in Regions I and II
8
9 observed. Hence, it seems unlikely that the differences in amounts of Ca and P are due to
10
11 differences in surface area of bioactive glass available for CDHA deposition. It is conceivable
12
13 that differences in ion release rates from the different bioactive glass preparations may have
14
15 played a role.
16
17

18
19
20
21 More Zn than Sr remained in composites after incubation in SBF for 28 days (Table 4). It is
22
23 conceivable that Zn released from bioactive glass may have been incorporated into newly
24
25 formed CDHA to a greater extent than Sr. Another possibility is that due to the greater extent
26
27 of mineral formation in composites containing A2Zn5, the diffusion of Zn out of composites
28
29 may have been impeded to a greater extent. Other factors may be differing affinities of GG for
30
31 Zn and Sr. A stronger affinity would lead to more retention within the hydrogel network.
32
33
34
35

36 5. Conclusion

37
38
39
40 Novel injectable, self-gelling composites of GG hydrogels containing 20% bioactive glass
41
42 were prepared by a simple mixing technique. Gelation occurred within an acceptable time
43
44 frame for injection (within 20 minutes). Composites containing the standard 45S5 bioactive
45
46 glass preparation were markedly less stiff. X-ray μ CT proved to be a technique capable of
47
48 detecting microparticles of diameter approximately 8 μ m, i.e. individual microparticles. The
49
50 size distribution of bioactive glass microparticles and their aggregates, and their distribution
51
52 in GG hydrogels, was visualized accurately using this high-resolution technique. A2, A2Zn
53
54 and A2Sr bioactive glass microparticles were more homogeneously dispersed in GG
55
56
57
58
59
60

1
2
3 hydrogels than those of the standard 45S5 preparation. Composites containing all four
4
5 bioactive glass preparations exhibited antibacterial activity against MRSA. Composites
6
7 containing, A2Zn and A2Sr bioactive glass preparations supported the adhesion and growth of
8
9 osteoblast-like cells and were considerably more cytocompatible than those of the standard
10
11 45S5 bioactive glass preparation. All composites underwent mineralization with CDHA upon
12
13 incubation in SBF. The extent of mineralization appeared to be greatest for composites
14
15 containing A2Zn and 45S5. The results underline the importance of the choice of bioactive
16
17 glass when preparing injectable, self-gelling composites.

1
2
3 The authors have no conflict of interest. No ethical approval was required for this study. No
4
5 part of this work has been previously published or submitted for publication elsewhere. The
6
7 authors made the following contributions to the paper:
8

9
10 Timothy E.L. Douglas conceived, designed, planned and coordinated the study, performed
11
12 rheometrical measurements (Figure S1b), interpreted the data and wrote the vast majority of
13
14 the manuscript, under the guidance of Andre G. Skirtach.
15

16 Michał Dziadek and Katarzyna Cholewa-Kowalska synthesized the bioactive glass
17
18 preparations A2, A2Zn₅ and A2Sr₅ (Table 1), performed zeta-potential measurements (Table
19
20 2), incubation studies in SBF and subsequent FTIR and SEM analysis (Figures 4, 5), and ICP-
21
22 OES studies of SBF after composite incubation (Table 5).
23

24
25 Svetlana Gorodzha Venera Weinhardt, Tilo Baumbach, Maria A. Surmeneva and Roman A.
26
27 Surmenev performed X-ray μ CT measurements and interpreted the data (Figures 1, 2, S2, S3,
28
29 S4, S5).
30

31
32 Jana Lišková and Lucie Bačáková performed cell biological characterization and
33
34 interpretation of these results in context with the material properties (Figure 3a, b, c).
35

36 Gilles Brackman and Tom Coenye performed antibacterial testing (Figure 3d).
37

38 Chris Vervaet and Valérie Vanhoorne performed laser diffraction measurements (Figure S1a).
39

40 Lieve Balcaen, Maria del Rosario Florez Garcia and Frank Vanhaecke performed ICP-OES
41
42 analysis (Tables 3 & 4).
43

44
45 Aldo R. Boccaccini provided 45S5 bioactive glass and contributed substantially to data
46
47 interpretation.
48

49 All authors contributed to writing parts of the paper and provided corrections as appropriate
50
51 for preparation of the final version of the manuscript.

9. Figures and Figure captions

Figure 1. X-ray μ CT-based visualization of hydrogel-bioactive glass composites. a)

Transverse sections through two different [heights \(close to the top and close to the bottom\) for](#) each composite type. b) 3D [rendering](#) of composite type. GG hydrogels without bioactive glass served as controls.

Figure 2. X-ray μ CT-based analysis of sizes of bioactive glass microparticles and

microparticle aggregates present in composites. a) [Logarithmic histograms](#) displaying size distributions of microparticles/aggregates in composites. b) Pie charts showing percentage of [a total](#) number of microparticles/aggregates in each size region.

Figure 3. Cell biological and antibacterial testing of hydrogel-bioactive glass composites. a)

columns, from left to right: A2, A2Zn5, A2Sr5, 45S5. Top row: MG-63 cells cultured directly on composites after 3 days. Middle row: cells cultured directly on composites after 7 days.

Bottom row: cells cultured on the bottom of the same well with the composite (in eluates) for

7 days. Scale bar = 200 μ m in all images. b) Proliferation on composites after 7 days. Values

are expressed as percentages of control values. *: $p < 0.05$ relative to control (Ctrl), #: $p <$

0.05 relative to composite containing 45S5, §: $p < 0.05$ relative to composite containing

A2Sr5. c) Proliferation of cells cultured for 7 days in eluates from composites, both undiluted

and diluted by factors of 2, 4 and 8. Values are expressed as percentages of control values. *:

$p < 0.05$ relative to control. d) Colony-forming units (CFU) of MRSA cultured in the presence

of composites [for 24 h](#). *: $p < 0.05$ relative to GG hydrogel without bioactive glass (CTRL

1
2
3 GG); $p < 0.05$ relative to A2, A2Zn5 and A2Sr5. Error bars show standard deviation in all
4
5 sub-diagrams.

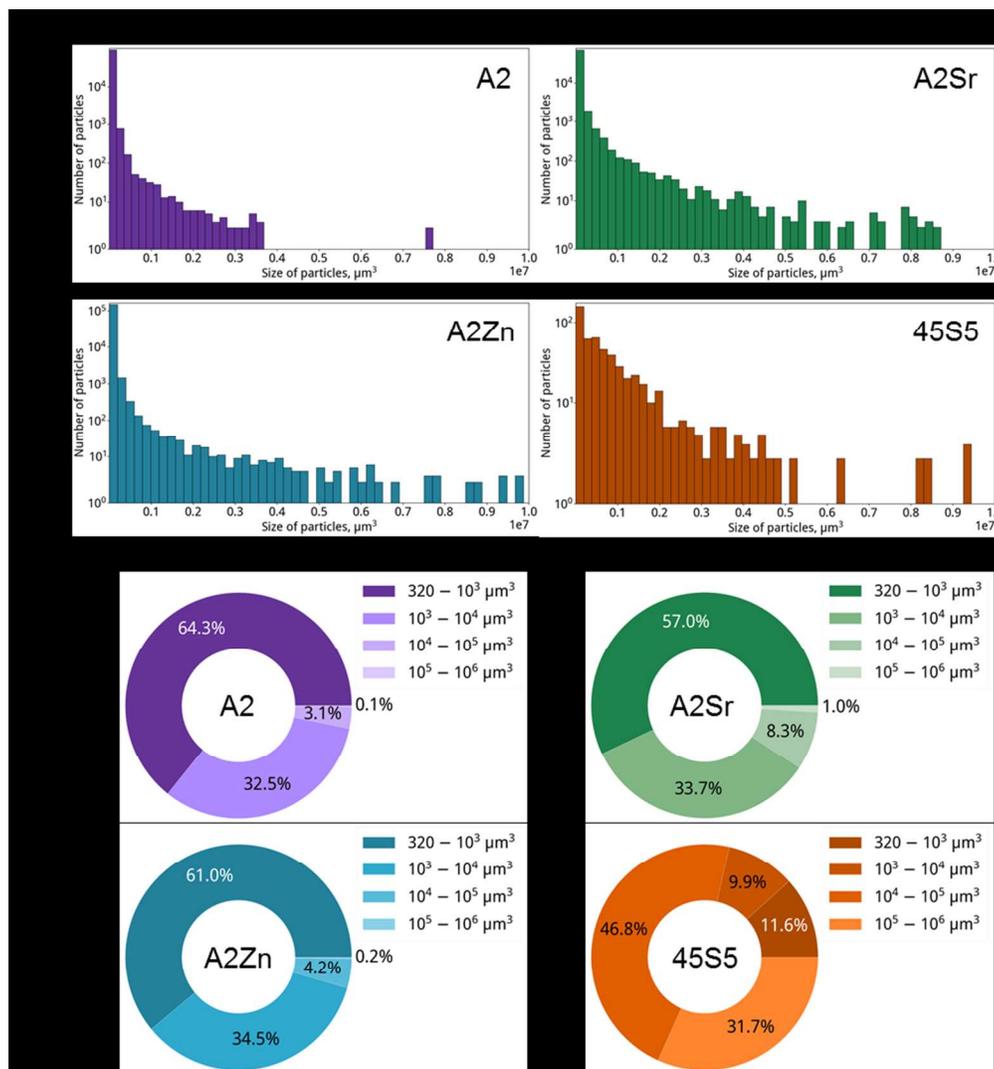

Figure 2. X-ray μCT-based analysis of sizes of bioactive glass microparticles and microparticle aggregates present in composites. a) Logarithmic histograms displaying size distributions of microparticles/aggregates in composites. b) Pie charts showing percentage of a total number of microparticles/aggregates in each size region.

85x91mm (300 x 300 DPI)

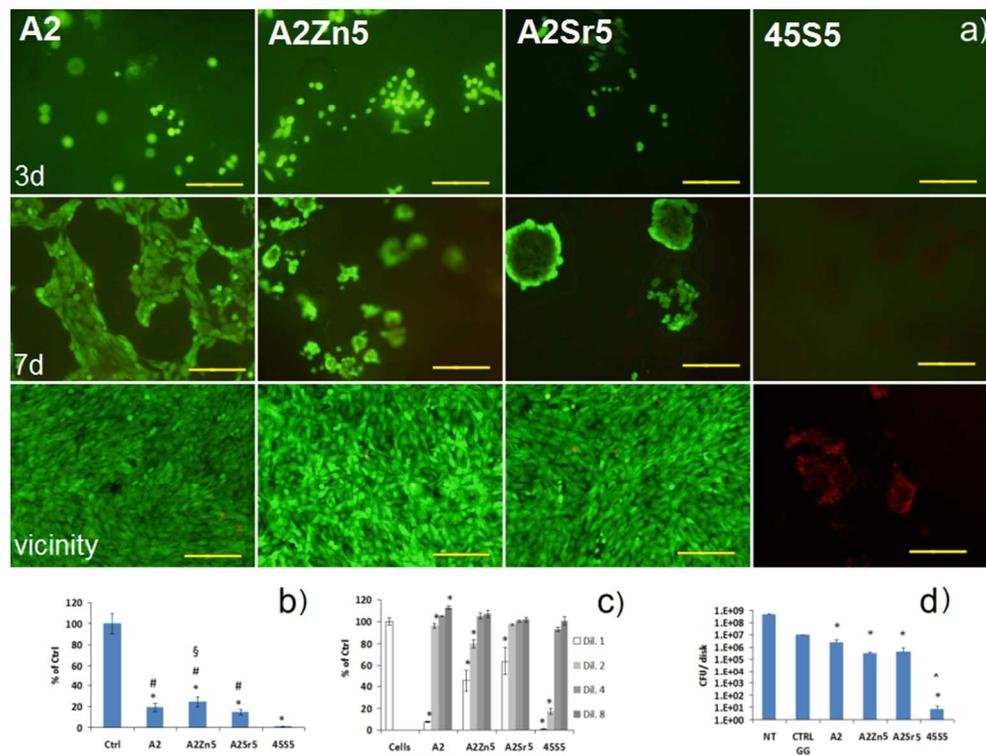

Figure 3. Cell biological and antibacterial testing of hydrogel-bioactive glass composites. a) columns, from left to right: A2, A2Zn5, A2Sr5, 45S5. Top row: MG-63 cells cultured directly on composites after 3 days. Middle row: cells cultured directly on composites after 7 days. Bottom row: cells cultured on the bottom of the same well with the composite (in eluates) for 7 days. Scale bar = 200 μm in all images. b) Proliferation on composites after 7 days. Values are expressed as percentages of control values. *: $p < 0.05$ relative to control (Ctrl), #: $p < 0.05$ relative to composite containing 45S5, §: $p < 0.05$ relative to composite containing A2Sr5. c) Proliferation of cells cultured for 7 days in eluates from composites, both undiluted and diluted by factors of 2, 4 and 8. Values are expressed as percentages of control values. *: $p < 0.05$ relative to control. d) Colony-forming units (CFU) of MRSA cultured in the presence of composites for 24 h. *: $p < 0.05$ relative to GG hydrogel without bioactive glass (CTRL GG); ^: $p < 0.05$ relative to A2, A2Zn5 and A2Sr5. Error bars show standard deviation in all sub-diagrams.

82x62mm (300 x 300 DPI)

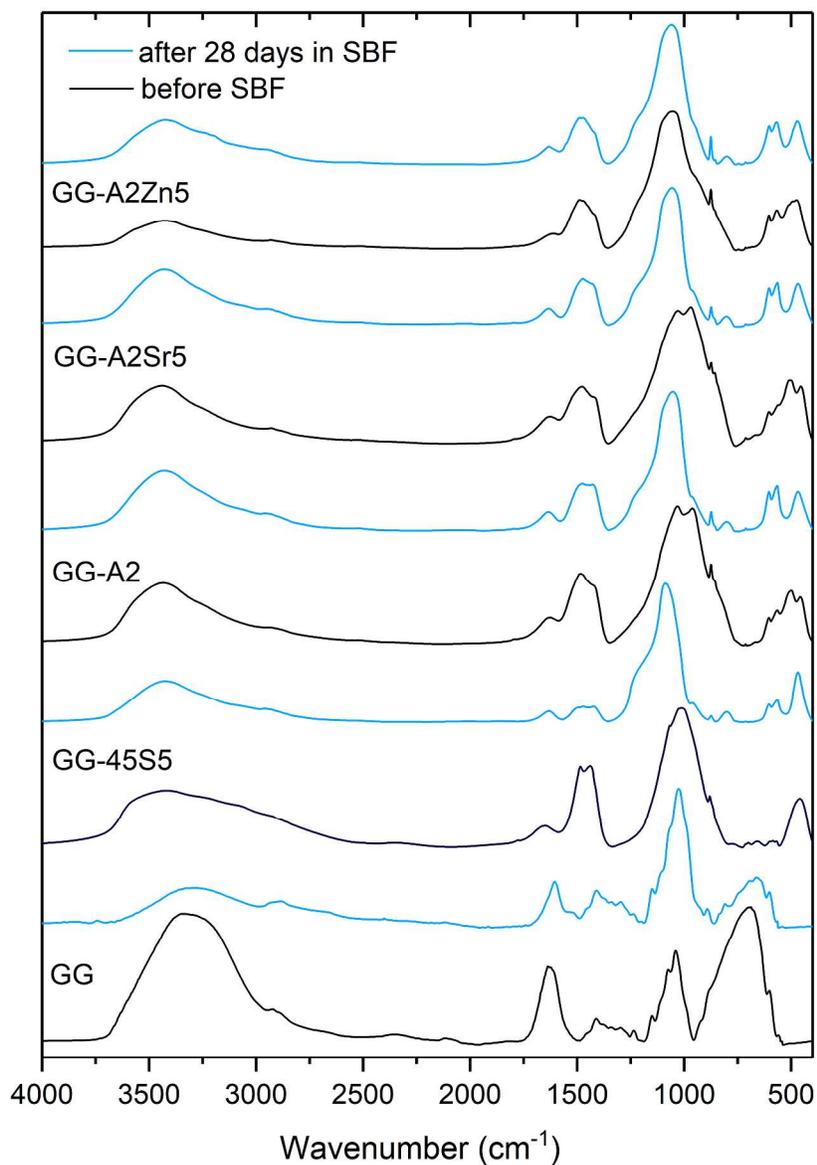

Figure 4. FTIR spectra of hydrogel-bioactive glass composites before and after incubation in SBF for 28 days.

238x334mm (300 x 300 DPI)

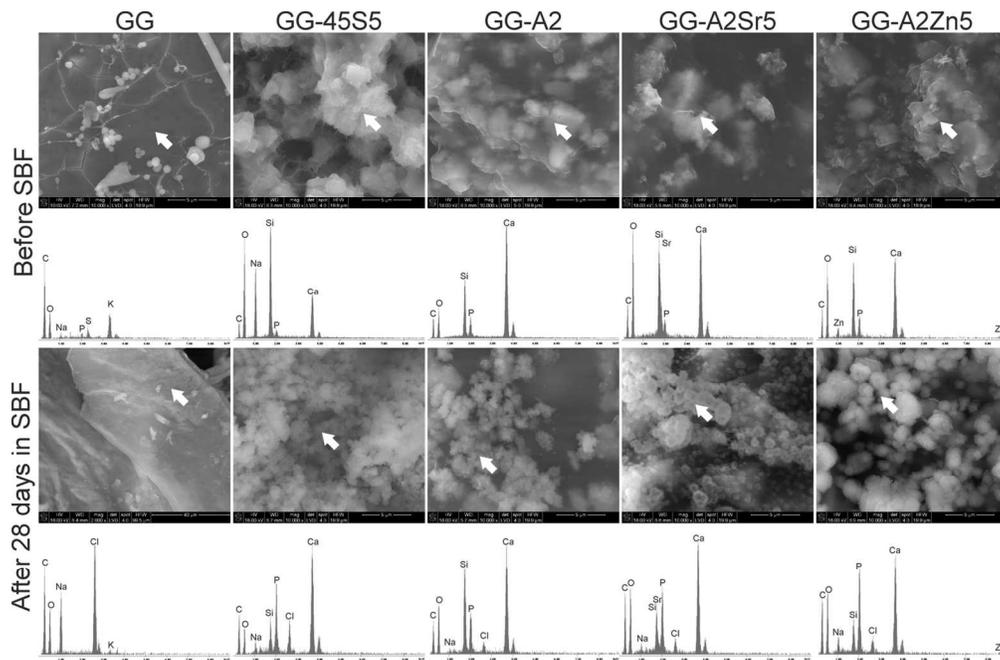

Figure 5. SEM images and EDX spectra (collected at the point indicated by arrow) of hydrogel-bioactive glass composites before and after 28-day incubation in SBF.

127x83mm (300 x 300 DPI)
