

The Psycholinguistic Markers of Single Word Recognition for Adult Learners of Literacy

Emma Mills
Lancaster University, England

Dr. Robert Davies
Lancaster University

Dr. Anna Woollams
Manchester University

Question?

DDM focusses on per subject model parameters and their variation to describe influence of person-level variables

Q: Is it feasible to perform a DDM for **item words**, to be able to use the language level variables as predictors

(Scraping data from megastudies for contrast...)

Does language experience help?

Main study:

- 218 participants
 - 11-12 yrs
 - 16-19 yrs
 - Adults
- 3 time points
 - 6 ability measures
 - 4 tasks

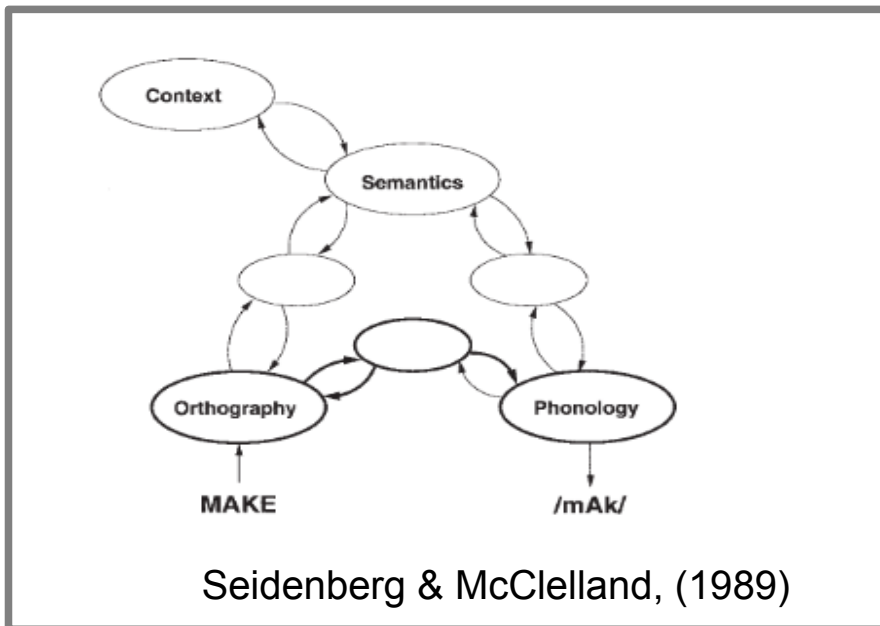

Does language experience help?

Main study:

4 Tasks

- 218 participants
 - 11-12 yrs
 - 16-19 yrs
 - Adults
 - 3 time points
 - 6 ability measures
 - 4 tasks
- Letter search
 - Lexical decision
 - Word naming
 - Sentence completion

Variables: **Person** & **Language** Level

Variables: **Person** & **Language** Level

Phonological

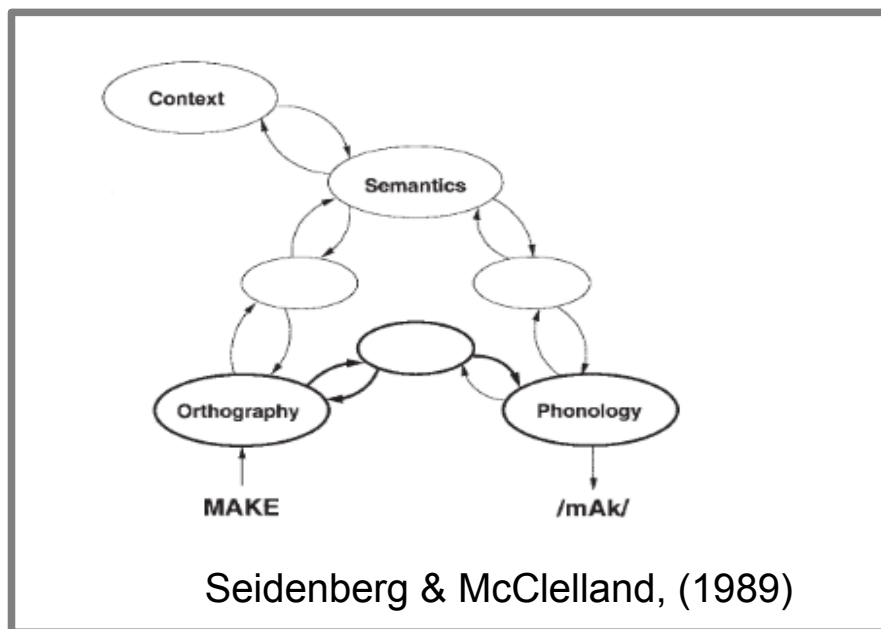

TOWRE nonword
Spelling
Phonological awareness
No. of phonemes
Bigram frequency

Semantic

Vocabulary
No. of synonyms
Semantic diversity
Imageability / Concreteness

Orthographical

TOWRE word
Frequency
No. of letters
Consistency
Neighbourhood rating

Drift Diffusion Modelling

Assumptions:

Binary decision tasks

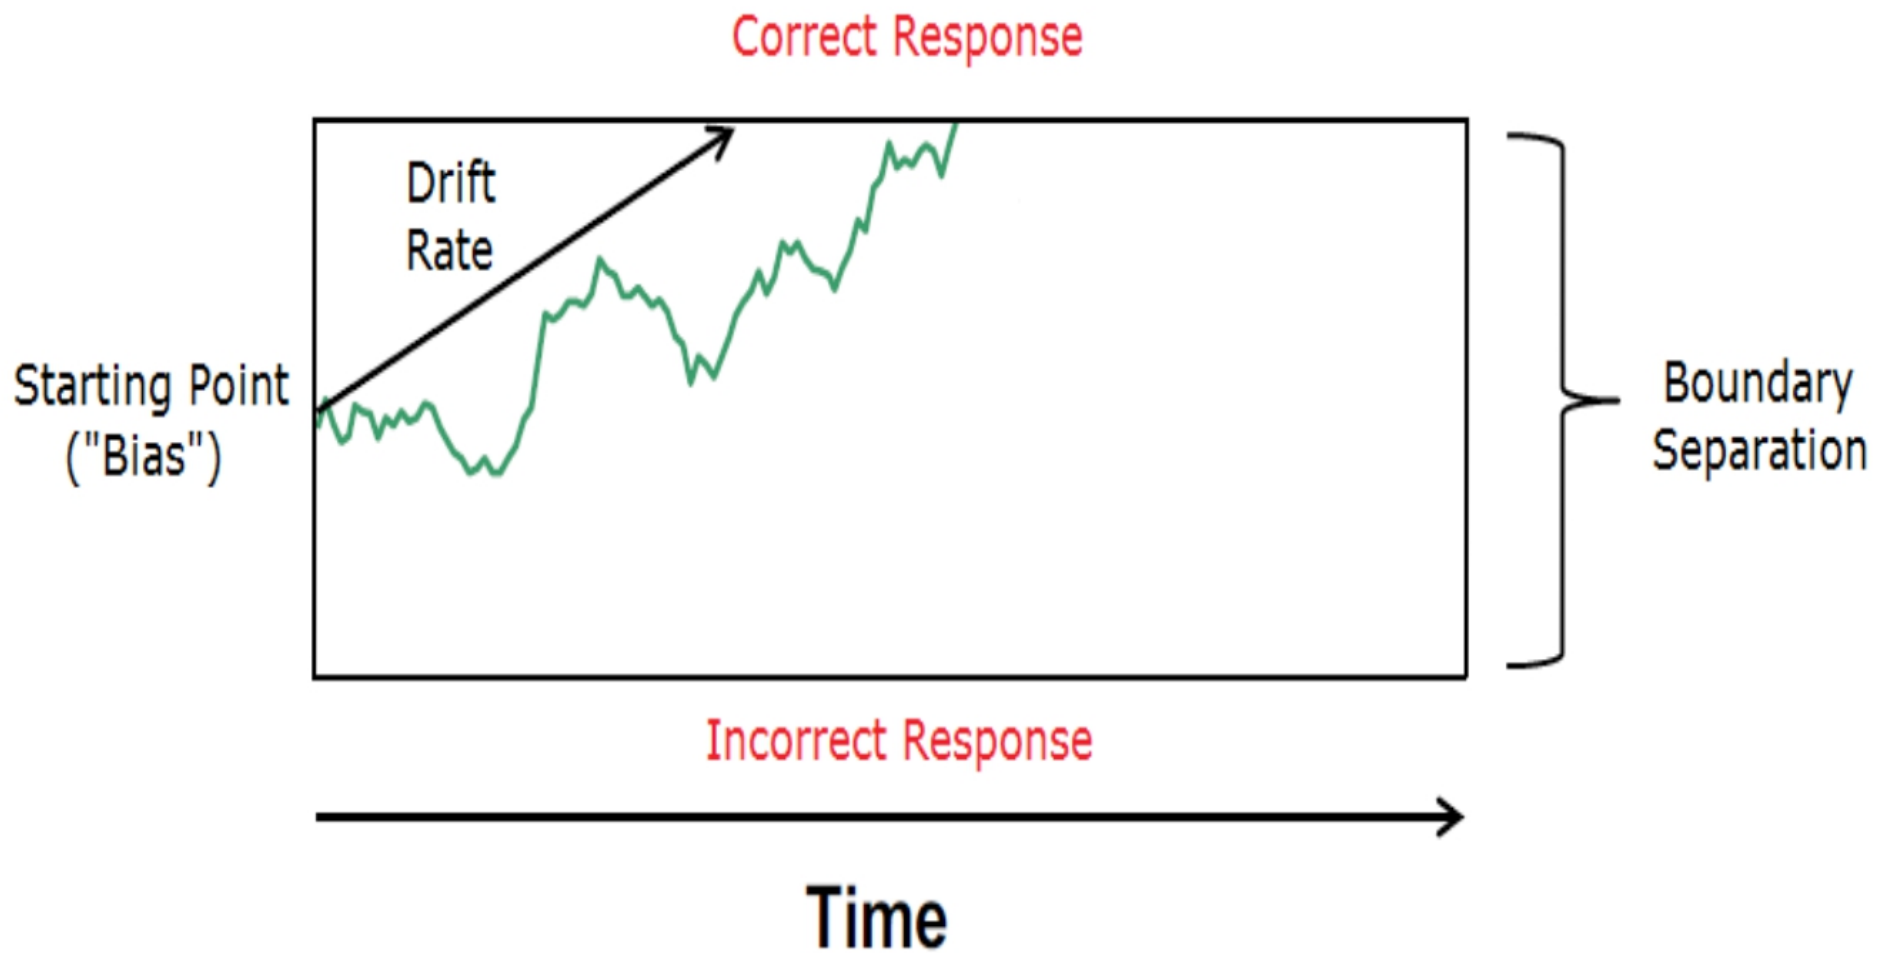

Continuous sampling of information over time

Single stage decisions

Consistency of parameter values over time

Relevance...

- DDM provides simultaneous modelling of response times and accuracy values
- Can handle conditions within one analysis
- May give an insight into approaching word reading because of the different parameters AND the variables of influence

Model parameters...

- Drift rate
- Boundary separation or Threshold
- Starting point
- Non-decision component

Image from Pedersen, Frank & Biele (2017),
The drift diffusion model as the choice rule in reinforcement learning.

Pilot study data

- 16-19 yrs (n = 12) – Summer 2016
- Adult data (n = 18) – Summer 2016
- 11-12 yrs (n = 14) – Summer 2017
- 6 ability measures

Pilot Study Data

- Lexical decision task
- Fast-dm software (Voss, Voss & Lerche, 2015)
- Linear regression in R (2018), using 'LanguageR', 'gvlma' and 'effects' packages

Modelling steps

- Lexical decision responses are reduced to parameter values per subject = sparse data
 - Drift rate for words and non-words
 - Starting point
 - Boundary values
 - Non-decision component
- Passed to linear regression models as outcomes with ability measures are predictors
- Model selection using AIC and principles of parsimony

Drift Rate for Words

16 yrs & Adults

Word Reading

Boundary Values...16 & Adults

Boundary Values...11-12 yrs

Boundary comparison

16 yrs & Adults

11 – 12 yrs

Non-Decision Component...

11-12 yrs only

To summarise...think broad brush strokes

- There appears to be group differences in predictors for the Word Drift Rate and Start Position....
- In Start Position, nonword reading for older people and phonological awareness plus spelling for younger people may reflect a developmental trajectory in grain size
- Age, Vocabulary and Spelling are shared for NonWord Drift Rate – with the older participants able to use it more efficiently
- The shared predictors for Boundary appear to be similar in effect

Questions: Q-Diffusion Model...

$$P(x_{pi} = 1 | \theta_p, \gamma_p) = \frac{\exp\left(\frac{\gamma_p \theta_p}{a_i v_i}\right)}{1 + \exp\left(\frac{\gamma_p \theta_p}{a_i v_i}\right)} \text{ with } \gamma_p, a_i, \theta_p, v_i \in \mathbb{R}^+$$
