Keywords: University Timetabling · Hybrid Learning · Mixed Integer Programming

1 Introduction

The COVID-19 pandemic artificially reduced the already limited capacity of physical spaces at universities. It forced a greater use of hybrid learning, which is a mode of teaching that combines online and in-person elements. Previous studies dealt with limited capacity by controlling the quantity and flow of students on campus \cite{5} or on the areas surrounding campus \cite{1}. Other studies investigated what policy changes allow a better use of resources \cite{2}.

Online classes are one way to reduce demand for physical space. Universities in the future will likely continue to offer a mix of online and in-person classes beyond the pandemic \cite{3}. Since students and staff typically prefer to attend classes in-person, this motivates the need to limit the number of classes held online, whilst still taking advantage of their ability to reduce the demand for physical space. More specifically, the problem is to investigate how universities can maximise the number of courses that they offer, whilst simultaneously limiting the number of online classes that are used to achieve this. This timetabling problem differs to the classic timetabling problem in that the input is a list of classes, but not all classes need to be assigned. Solutions to this problem identify how many courses could be offered, which is useful information for universities planning semesters. The preliminary model presented in this paper illustrates one way of solving this particular problem.

2 Model Formulation

Timeslots are lengths of time that have a start and end. In this problem we assume these are five minutes long. Timesets are defined as a subset of the set of all timeslots. These are used to better model complicated arrangements. For example, a timeset could describe a two hour class meeting every other week. Table \ref{table:notation} provides the notation for the sets used within the formulation of the model.

We define the matrix $A$ where the entry $A_{r_1,r_2}$ is equal to the number of timeslots it takes to travel from room $r_1$ to room $r_2$. In particular, for $d$ a non-negative integer, $A_{r_1,r_2} = d$ represents a travel time of $5d$ minutes.
Table 1. Key notation. The first six sets are primarily used to describe elements of the problem, the last seven sets are primarily used in the construction of constraints.

</tbody>
</table>

The set \(C\) contains all classes regardless of if they can be held online, in-person or both. The online space is modelled as a room that is always available and can host multiple classes at the same time. Let \(r^*\) represent this online space. A class, \(c \in C\), can be held online if and only if \(r^* \in R_c\). For \(r^*\) assume that \(A_{r^*,r^*} = 0\) and \(A_{r^*,r} = d^*\) for all \(r \in R \setminus r^*\) where \(d^*\) is a fixed number of timeslots. For this paper, we assume any class can happen online and that \(d^* = 0\).

### 2.1 Definition of variables

One set of variables used in this problem are binary variables indicating if a class is assigned to a particular room and timeset. They are defined as follows:

\[
x_{c,r,t} = \begin{cases} 
1 & \text{Class } c \in C \text{ is held in room } r \in R \text{ in timeset } t \in T, \\
0 & \text{Otherwise.}
\end{cases}
\]

The second set of variables are binary variables that indicate if a class uses a room, or if a class uses a timeset. They are defined as follows:

\[
y_{c,r} = \begin{cases} 
1 & \text{Class } c \in C \text{ is held in room } r \in R, \\
0 & \text{Otherwise.}
\end{cases}
\]

\[
y_{c,t} = \begin{cases} 
1 & \text{Class } c \in C \text{ is held in timeset } t \in T, \\
0 & \text{Otherwise.}
\end{cases}
\]

These variables are related to each other by linking constraints:

\[
y_{c,t} = \sum_{t \in T} x_{c,r,t}, \quad \forall r \in R, c \in C,
\]
\[ y_{c,t} = \sum_{r \in R} x_{c,r,t}, \quad \forall t \in T, c \in C. \]

We also define binary variables to indicate if courses are offered:

\[ g_k = \begin{cases} 1 & \text{Course } k \in K \text{ is offered,} \\ 0 & \text{Otherwise.} \end{cases} \]

**Parameter arrays** Defined in Table 2, parameter arrays are fully determined by a given problem instance. They are used to indicate if a group of resources satisfy a particular condition, thus indicating what constraints to include in the model corresponding to that instance.

### Table 2. Definition of each parameter array. t, t₁ and t₂ are in the set T. r, r₁ and r₂ are in the set R

<table>
<thead>
<tr>
<th>Array</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(D_0)</td>
<td>A matrix where (D_0[r,t]) is equal to one if room (r) is unavailable at some point during timeset (t), zero otherwise</td>
</tr>
<tr>
<td>(D_1)</td>
<td>An array where (D_1[r_1,r_2,t_1,t_2]) is equal to one if there is not enough time between (t_1) and (t_2) to travel between (r_1) and (r_2), zero otherwise</td>
</tr>
<tr>
<td>(D_2)</td>
<td>A matrix where (D_2[t_1,t_2]) is equal to zero if the first meeting in (t_1) concludes before the start of the first meeting in (t_2), one otherwise</td>
</tr>
<tr>
<td>(D_3)</td>
<td>A matrix where (D_3[t_1,t_2]) is zero if the meetings in (t_1) and (t_2) do not occur on overlapping weeks and days, if any meeting in (t_1) and (t_2) occurs on the same day and week then (D_3[t_1,t_2]) is equal to the number of timeslots between the start of the earliest meeting and end of the latest</td>
</tr>
<tr>
<td>(D_4)</td>
<td>A matrix where (D_4[t_1,t_2]) is equal to zero if (t_1) and (t_2) start at the same time of day, one otherwise</td>
</tr>
<tr>
<td>(D_5)</td>
<td>A matrix where (D_5[t_1,t_2]) is equal to zero if (t_1) completely overlaps (t_2) in the times of day they meet or vice versa, one otherwise</td>
</tr>
<tr>
<td>(D_6)</td>
<td>A matrix where (D_6[t_1,t_2]) is equal to zero if (t_1) meets on a subset of days that (t_2) does or vice versa, one otherwise</td>
</tr>
<tr>
<td>(D_7)</td>
<td>A matrix where (D_7[t_1,t_2]) is equal to zero if (t_1) and (t_2) do not meet on any of the same days, one otherwise</td>
</tr>
<tr>
<td>(D_8)</td>
<td>A matrix where (D_8[t_1,t_2]) is equal to one if (t_1) overlaps (t_2), zero otherwise</td>
</tr>
</tbody>
</table>

### 2.2 Constraints

There are various constraints that need to be included within any university timetabling model. Some are more specialised so that the timetable adheres to university policy or allows students and staff to travel comfortably between classes. In this section, some constraints included within our model are described.
Most of these constraints have been proposed in the existing timetabling literature \[4\] and what is presented in this paper is our approach to modelling these constraints.

**Classes can only be assigned at most a single room and a single timeset**

\[
\sum_{t \in T} \sum_{r \in R} x_{c,r,t} \leq 1, \quad \forall c \in C.
\]

**Classes can only be assigned compatible rooms and times**

To ensure only compatible rooms and times are used, for each \(c \in C\) add the following constraints:

\[
\sum_{r \in R} x_{c,r,t} = 0, \quad \forall t \in T \setminus T_c.
\]

\[
\sum_{t \in T} x_{c,r,t} = 0, \quad \forall r \in R \setminus R_c.
\]

**Classes should not happen in a room when that room is not available**

\[
\sum_{t \in T} \sum_{r \in R} D_0[r,t]x_{c,r,t} = 0, \quad \forall c \in C.
\]

**In-person classes should not use the same room at the same time**

\[
\sum_{c \in C} \sum_{t \in O_s} x_{c,r,t} \leq 1, \quad \forall r \in R \setminus r^*, s \in S.
\]

**Group of classes should occur in the same room**

Let \(G\) be a set of classes that must occur in the same room. For each \(r \in R_G\) define a binary variable \(s_r^G\) that takes the value one if every class in \(G\) uses room \(r\) and zero otherwise. Add the following constraints:

\[
\sum_{c \in G} y_{c,r} = |G|s_r^G, \quad \forall r \in R_G,
\]

\[
\sum_{r \in R_G} s_r^G \leq 1,
\]

\[
y_{c,r} = 0, \quad \forall r \notin R_G, c \in G.
\]

**Attending a group of classes**

Staff and students have collections of classes they must attend. Denote a collection of classes as \(G\). For each \((c_1, c_2) \in C_G\) add the following constraints:

\[
D_1[r_1, r_2, t_1, t_2](x_{c_1,r_1,t_1} + x_{c_2,r_2,t_2}) \leq 1, \quad \forall t_1 \in T_{c_1}, t_2 \in T_{c_2}, r_1 \in R_{c_1}, r_2 \in R_{c_2}.
\]

**Group of classes should occur in a certain order**

Let \(G\) be a sequence of classes that should occur in order, meaning that the first meeting of a class should completely finish before the start of the next class. Suppose \(G = (c_1, c_2, \ldots, c_k)\), then for each pair \((c_i, c_{i+1})\) where \(i \in \{1, \ldots, k-1\}\) add the following constraints:

\[
D_2[t_1, t_2](y_{c_i,t_1} + y_{c_{i+1},t_2}) \leq 1, \quad \forall t_1 \in T_{c_i}, t_2 \in T_{c_{i+1}}.
\]
Group of classes should be grouped within a period of time  Let \( G \) be a set of classes that should all happen within \( H \) timeslots if they happen on the same day and week. For each \((c_1, c_2) \in C_G\) add the following constraints:

\[
I(D_3[t_1, t_2] > H)(y_{c_1, t_1} + y_{c_2, t_2}) \leq 1, \quad \forall t_1 \in T_{c_1}, t_2 \in T_{c_2},
\]

where \( I \) is an indicator function that takes the value one if \( D_3[t_1, t_2] > H \) holds and zero otherwise.

Timing constraints  All timing specific constraints have the same form. Suppose \( G \) is the set of classes the constraint applies to. For each \((c_1, c_2) \in C_G\) add the following constraints:

\[
D[t_1, t_2](y_{c_1, t_1} + y_{c_2, t_2}) \leq 1, \quad \forall t_1 \in T_{c_1}, t_2 \in T_{c_2},
\]

where \( D \) is the appropriate parameter array for that constraint. Table 3 describes a constraint on a group of classes and the associated parameter array.

<table>
<thead>
<tr>
<th>Constraint</th>
<th>Associated ( D )</th>
</tr>
</thead>
<tbody>
<tr>
<td>Classes should start at the same time</td>
<td>( D_4 )</td>
</tr>
<tr>
<td>Classes should occur during the same time of day</td>
<td>( D_5 )</td>
</tr>
<tr>
<td>Classes should occur on the same days of the week</td>
<td>( D_6 )</td>
</tr>
<tr>
<td>Classes should occur on the different days of the week</td>
<td>( D_7 )</td>
</tr>
<tr>
<td>Classes should not overlap in time</td>
<td>( D_8 )</td>
</tr>
</tbody>
</table>

Course structure constraints  Courses can be split into sections that teach identical content. Sections are a collection of classes and it is possible for two sections of the same course to share classes. We define binary variables to indicate if a course section is offered:

\[
h_{k,l} = \begin{cases} 1 & \text{Section } l \in L_k \text{ of course } k \in K \text{ is offered,} \\ 0 & \text{Otherwise.} \end{cases}
\]

For a given course, \( k \in K \), a section \( l \in L_k \) can be offered only if all of the classes in that section are offered. This is modelled by the following constraints:

\[
h_{k,l} \leq \frac{1}{|l|} \sum_{c \in l} \sum_{t \in T} \sum_{r \in R} x_{c,r,t}, \quad \forall l \in L_k, k \in K,
\]

where \(|l|\) is the number of classes in a section. A course is only offered if there is at least one section being offered. This is modelled by the following constraints:

\[
g_k \leq \sum_{l \in L_k} h_{k,l}, \quad \forall k \in K.
\]
2.3 Objectives

There are many objectives in the timetabling literature. In this section some of the objectives that could be used within this model are presented.

**Maximise number of courses offered**

\[
\max z_1 = \sum_{k \in K} g_k,
\]

**Maximise number of classes held**

\[
\max z_2 = \sum_{c \in C} \sum_{t \in T_c} \sum_{r \in R_c} x_{c,r,t}.
\]

Whilst courses are important, offering as many classes as possible provides flexibility within these courses.

**Minimise number of classes held online**

\[
\min z_3 = \sum_{c \in C} \sum_{t \in T_c} x_{c,r^*,t}.
\]

Ideally, there would be no need for online classes but it cannot be ignored that they can help increase \(z_1\) because they are not subject to physical space limitations, a common limit to teaching capacity.

**Minimise cost of assignment**

\[
\min z_4 = \sum_{c \in C} \left( \sum_{r \in R_c} P_{c,r} y_{c,r} + \sum_{t \in T_c} P_{c,t} y_{c,t} \right),
\]

where \(P_{c,r}\) and \(P_{c,t}\) are non-negative penalties for assigning class \(c \in C\) to room \(r \in R_c\) and timeset \(t \in T_c\) respectively. The exact value of these penalties are subjective in practice. They could represent:

- Actual monetary cost of using the resource.
- Approximation of preference (low penalty indicating higher preference).
- Arbitrarily large penalties to deter solution from using a resource.

**Weighted objective approach**

\[
\max \ z = w_1 z_1 + w_2 z_2 + w_3 z_3 + w_4 z_4,
\]

where \(w_1\) and \(w_2\) are non-negative weights, and \(w_3\) and \(w_4\) are non-positive weights. By properly tuning these weights the model is able to determine an optimal mix of in-person and online teaching.
3 Results

To verify that this model produces feasible timetables, three instances from the 2019 International Timetabling Competition (ITC-2019) were used [4]. Described in Table 4 is the number of classes, timesets and rooms for each instance.

The problem defined in the ITC-2019 involves creating a complete timetable and allocating students to classes based on their course requests. Our model does not consider student allocation nor requires a complete timetable to be constructed. Therefore, in this experiment, we maximise \( z_2 \) only. Using this solution, it is possible to evaluate \( z_3 \) and \( z_4 \).

For our experiments we used an internal computing node running CentOS Linux with an Intel Xeon E5-2699 v3 CPU running at 2.30GHz and 528GB of RAM. The model was implemented in Python 3.5 and solutions were found using the commercial solver Gurobi 9.0, which successfully produced valid timetables. Table 4 provides information about each solution.

Table 4. The problem instances and quantities of key features. In the “Type” column, “T” indicates “test” instances and “C” indicates “competition” instances. The \( z_3 \) recorded is the number of classes that does not require a room, which we treat as “online-only” classes. The \( z_4 \) recorded here is the same value reported by the ITC-2019 validation tool [4].

| Instance  | Type | \(|K|\) | \(|C|\) | \(|T|\) | \(|R|\) | \(z_2\) | \(z_3\) | \(z_4\) | Time (s) |
|-----------|------|--------|--------|--------|--------|--------|--------|--------|---------|
| lums-sum17 | T    | 19     | 20     | 93     | 62     | 20     | 0      | 73     | 0.003   |
| bet-sum18  | T    | 48     | 127    | 50     | 46     | 127    | 6      | 3502   | 0.011   |
| tg-fal17   | C    | 36     | 711    | 1645   | 23     | 711    | 15     | 9610   | 58757.559 |

As can be seen from Table 4, in all three instances \(|C| = z_2\) meaning that our solutions are optimal for this objective. Since we are offering all possible classes, it is clear that it is possible to offer every course.
