ABSTRACT

This paper investigates the development of relative clauses in the
speech of one German-speaking child aged 2;0 to 5;0. The earliest
relative clauses we found in the data occur in topicalization
constructions that are only a little different from simple sentences:
they contain a single proposition, express the actor prior to other
participants, assert new information and often occur with main-clause
word order. In the course of the development, more complex relative
constructions emerge, in which the relative clause is embedded in a
fully-fledged main clause. We argue that German relative clauses
develop in an incremental fashion from simple non-embedded
sentences that gradually evolve into complex sentence constructions.

INTRODUCTION

The acquisition of relative clauses has been studied extensively over the past
forty years (e.g. Sheldon, 1974; Tavakolian, 1981; Goodluck & Tavakolian,
1982; Hamburger & Crain, 1982; Clancy, Lee & Zoh, 1986; Crain, McKee
& Emilliani, 1990; Corrêa, 1995; Goodluck & Stojanović, 1997; McKee,

McDaniel & Snedeker, 1998; Diessel & Tomasello, 2000, 2005; Kidd & Bavin, 2002; Diessel, 2004; Ozeki & Shirai, in press). Most of these studies investigate the acquisition of relative clauses in the framework of generative grammar. Diessel (2004) and Diessel & Tomasello (2000, 2005) provide the first usage-based analysis of the development of relative clauses, in which constructions are the basic elements of grammar. A construction is a complex linguistic sign combining a grammatical pattern with a particular meaning (cf. Goldberg, 1995). Using corpus data from four English-speaking children aged 2;0 to 5;0, Diessel & Tomasello observed that children's early relative clauses appear in presentational constructions consisting of a copular clause and a finite or non-finite relative clause in which the subject is gapped or relativized, as in the following examples (cf. Diessel, 2004: 131, 139):

(1)   Here's a tiger **that**'s gonna scare him.
(2)   This is the sugar **that** goes in there.
(3)   This is the horse sleeping in a cradle, their bed.
(4)   Dere's was a kitty walking by.

Although these sentences consist of two clauses, they describe only a single state of affairs. The copular clause does not denote an independent situation, but functions to focus the interlocutors' attention on a particular referent that is semantically integrated in the relative clause (cf. Lambrecht, 1988). Since the relative clause contains the only proposition, it is semantically more elaborated than the copular clause; very often the relative clause asserts new information like a main clause. Starting from such simple structures, children gradually produce more complex relative constructions that become increasingly different from simple main clauses. The whole development can be characterized as a process of clause expansion whereby a simple sentence is gradually transformed into a bi-clausal construction (cf. Diessel, 2004).[1]

Interestingly, there are a number of studies suggesting that the development of relative clauses in other languages takes a similar pathway. For instance, Dasinger & Toupin (1994) noticed the predominance of presentational relative constructions in the speech of Spanish- and Hebrew-speaking children, which they collected in a picture book task, and Hudelot (1980) reports that the vast majority of children's spontaneous

[1] Analyzing data from five English-speaking children aged 2;0 to 5;0, Diessel (2004) argues that all complex sentences evolve from simple non-embedded sentences but that two different developmental pathways must be distinguished: complex sentences including complement and relative clauses evolve from simple sentences that are gradually EXPANDED to multiple-clause constructions, whereas complex sentences including adverbial and coordinate clauses develop from simple sentences that are INTEGRATED into a biclausal structure.

relative clauses in French are attached to the predicate nominal of a copular clause. Moreover, Hermon (2005) argued that there are striking parallels in the development of relative clauses in English and Indonesian: like English-speaking children, Indonesian-speaking children begin to produce relative clauses in structures that denote only a single state of affairs.

Generalizing across these studies, one might hypothesize that there is a general cross-linguistic pattern of development whereby relative clauses evolve from simple non-embedded sentences.[2] Starting from this hypothesis, the current paper examines the development of relative clauses in German. First, we will discuss formal and functional differences and similarities between embedded and non-embedded clauses in German. Then we will investigate how the similarities might facilitate the step from the use of non-subordinate main clauses to subordinate relative clauses.

German is a so-called verb-second language, in which the main clause includes the finite verb in second position;[3] but in subordinate clauses the finite verb occurs after all other elements at the end of the clause. This makes the development of German relative clauses particularly interesting in the light of the above hypothesis: if German relative clauses evolve from simple non-embedded sentences, like relative clauses in English, it seems reasonable to assume that the development of German relatives originates from grammatical constructions with main clause (i.e. verb-second) word order.

In German grammar, relative clauses are commonly defined as subordinate clauses including the finite verb in final position; but the position of the finite verb is only one of the features that characterize German relative clauses. In addition, the following features must be taken into account: (1) relative clauses provide information about a nominal referent in the previous clause; (2) they include a case-marked relative pronoun that indicates the syntactic function of the nominal referent in the relative clause; (3) the relative pronoun is generally the first word in the relative clause; and (4) the antecedent of the relative pronoun is the immediately preceding NP (cf. Eisenberg, 2004). Interestingly, although all of these features are necessary to define German relative clauses, the

---

[2] That does not mean that relative clauses generally evolve from presentational constructions. In fact, Ozeki & Shirai (in press) have shown that in contrast to English-speaking children, Japanese-speaking children use relative clauses only rarely in presentational constructions. However, reanalyzing Ozeki & Shirai's data, Diessel (2007) argues that although the development of Japanese relative clauses does not originate from presentational constructions, early Japanese relatives occur in constructions that are similar to children's early relative constructions in English in that they contain only a single proposition.

[3] The position before the finite verb can be filled by any element, but the subject and certain types of adverbials are most common in preverbal position.

position of the finite verb is sometimes the only surface feature that distinguishes them from simple main clauses, as in the following examples:

(5) Da   ist Michael, der mir gestern   geholfen **hat**.
    There is Michael, who me yesterday helped   has
    'There is Michael who helped me yesterday.'
(6) Da   ist Michael, der   **hat** mir gestern   geholfen.
    There is Michael, who/he has me yesterday helped
    'There is Michael who helped me yesterday.'

On the surface, the sentences in (5–6) are identical except for the position of the finite verb: both sentences are combined by an anaphoric pronoun resuming the immediately preceding NP at the beginning of the second clause. However, based on the position of the finite verb, (5) can be classified as a complex sentence construction including a relative clause, whereas (6) consists of two main clauses combined by a case-marked anaphoric demonstrative pronoun that is morphologically indistinguishable from a relative pronoun. While the two constructions are commonly divided into separate clause types (based on the position of the finite verb), there can be no doubt that the verb-second construction in (6) resembles the relative construction in (5).[4] In fact, as can be seen in (7) there are verb-second constructions that are indistinguishable from relative clauses:

(7) Dort sitzt ein Mann, der   **schläft**?
    There sits a man, who/he sleeps
    'There is a man who is sleeping?'

Example (7) has the same structure as examples (5) and (6); it consists of two clauses that are combined by an anaphoric pronoun at the beginning of the second clause. But since the second clause includes only two words, the anaphoric pronoun and an intransitive verb, the position of the finite verb is not sufficient to indicate the clause type: the verb occurs in second position but is also the final element of the clause. In other words, example (7) is ambiguous between an interpretation as main and relative clause.

Since children are very sensitive to surface similarities (Gentner, 1989), it seems reasonable to assume that they recognize the structural overlap between main and relative clauses, which in turn may influence the acquisition process. More precisely, since there are main clauses that are only a little different from relative clauses, one might hypothesize that these constructions provide a starting point for the development of German relatives. Thus, we decided to include verb-second constructions into our database if they were only minimally different from relative clauses (see

---

[4] Historically, the two structures are related: German relative clauses developed from main clauses including an anaphoric demonstrative pronoun (cf. Diessel, 2006).

below). Following Gaertner (1998), we refer to these structures as V2-relatives, but without committing ourselves to a particular grammatical analysis.

Although V2-relatives do not exhibit the same syntactic properties as ordinary relative clauses (e.g. V2-relatives cannot be center-embedded), on the surface they are so similar to verb-final relatives that they are often classified as a particular type of relative clause (cf. Schuetze-Coburn, 1984; Lambrecht, 1994; Auer, 1998; Weinert, 2004). While this analysis may not be compatible with a theoretical approach in which main and subordinate clauses are discrete categories defined by syntactic tests, it can easily be accommodated by the usage-based approach, in which grammatical categories are grounded in the speaker's experience with language. Since experience-based categories are constantly changing (both in history and in the lifetime of a person), it is reasonable to assume a fluid transition between main- and subordinate clauses (cf. Lehmann, 1988; Diessel, 2004). In other words, while V2-relatives may not pass the categorical tests of relative clauses, they are relevant to the development of German relatives because they are at the borderline between main and subordinate clauses, which makes them interesting for our study.

If the acquisition of German relative clauses originates from simple sentences, as we hypothesize, V2-relatives may help the child to bootstrap from simple main clauses into complex relative constructions. Assuming that children draw on their previous knowledge of simple sentences in their first attempts to produce relative clauses, we would predict a developmental shift from V2-relatives to verb-final constructions. In other words, the particular properties of German relative clauses allow us to test our central hypothesis that the earliest relative clauses evolve through small extensions from simple main clauses.

In what follows, we describe the development of relative clauses in the speech of one German-speaking child aged 2;0 to 5;0. Concentrating on verb-final constructions, Rothweiler (1993) examined the development of German relatives in spontaneous child speech, but since her data include only a few dozen (verb-final) relatives collected from children after the age of 2;9, her data are not sufficient to characterize the early development of German relative clauses. Apart from Rothweiler's observational study, there are a few experimental studies on the acquisition of German relative clauses, but they concentrate on particular types of relative clauses and consider only older children (cf. Grimm & Wintermantel, 1975).

DATA

Our analysis is based on spontaneous utterances produced by a German-speaking boy, who we called Leo. Leo is growing up in a middle-class

family in Leipzig; his caregivers have higher education and speak Standard German. The data consist of 383 one-hour recordings of child–adult interactions between the ages of 2;0 and 5;0. During the first year of the study, the recordings were made five times a week and were supplemented by diary utterances collected by Leo's caregivers. After the age of 3;0, Leo was recorded five times a month. Overall, the corpus includes nearly half a million words and 6,300 diary utterances, which is the largest and densest database that has ever been compiled of a single child. The transcripts were automatically tagged by a German version of the CHILDES MOR-program (cf. MacWhinney, 2000), developed by Behrens (2000) and linked to the corresponding sound files.

Since we hypothesized that the development of relative clauses originates from simple main clauses, we searched for two target structures: ordinary relative clauses and V2-relatives, which we limited to constructions that are only minimally different from ordinary relative clauses (see below). The two target structures were identified by the following criteria:

- They consist of two finite clauses.
- The second clause provides information about a nominal referent in the previous clause.
- The second clause includes a case-marked anaphoric pronoun that indicates the syntactic function of the nominal referent in the second clause.
- The anaphoric pronoun is generally the first constituent in the second clause.
- The antecedent of the anaphoric pronoun is the immediately preceding NP.

V2-relatives are defined as constructions that differ from ordinary relative clauses only by the position of the finite verb. The following criteria were used to distinguish V2-relatives from structurally more distinct V2-constructions:

- V2-relatives include a demonstrative pronoun that is formally indistinguishable from a relative pronoun. Constructions including other types of pronouns were disregarded.
- V2-relatives include the demonstrative pronoun in the first position of the clause. Constructions including a demonstrative pronoun in a different position were disregarded.
- V2-relatives modify a nominal expression in the immediately preceding NP. Constructions in which a demonstrative pronoun is separated from the antecedent by a (non-attributive) NP were disregarded (if the immediately preceding NP includes an attributive

TABLE 1. *Total number of Leo's relative clauses*

Age	Total number of utterances in Leo's corpus	Total number of Leo's relative clauses
2;0–2;6	77,870	92 (0·12%)
2;6–3;0	55,921	309 (0·55%)
3;0–3;6	13,429	90 (0·67%)
3;6–4;0	11,574	96 (0·82%)
4;0–5;0	22,910	199 (0·86%)
Total	181,704	786 (0·43%)

     PP, the relative clause may be attached to a nominal expression across an intervening NP).

- V2-relatives serve to provide information about a nominal referent. Constructions functioning as questions or other types of speech acts were disregarded.

Using the PERL program we automatically extracted all structures from the transcripts that include a relative/demonstrative pronoun following a lexical NP.[5] The output of the search files was subsequently checked for mistakes by the first and second authors. Based on the criteria stated above, the first and second authors agreed on all target structures that were entered into the analysis. Since the PERL output contained utterances that did not qualify as relative clauses according to our definition, the first author compared one automatically extracted search file to a list of relative clauses that were manually extracted from one 1-hour recording. None of the manually extracted relative clauses were missing.

Overall, there are 786 child relative clauses in the transcripts. Table 1 provides an overview of the data. For demonstrating and investigating developmental shifts, we have divided the data into five broad age periods, namely 2;0–2;6, 2;6–3;0, 3;0–3;6, 3;6–4;0 and 4;0–5;0. As can be seen in this table, Leo begins to produce relative clauses very early (the first relative clause included in the transcripts appears at 2;2), but initially relative clauses are rare. Between the ages of 2;0 and 2;6, only 0·12% of Leo's utterances include a relative clause, but in the following years the proportion increases steadily up to a level of 0·86% between 4;0 and 5;0.

In addition to Leo's relative clauses, we collected and analyzed a subset of his caregivers' relative clauses. These data come from five different periods of the study, when Leo was 2;0, 2;7, 3;2, 3;9 and 4;10, and include a total of 330 relative clauses. Table 2 provides an overview of the caregivers' data. As can be seen in this table, the caregivers' utterances include a larger

---

[5] We would like to thank Franklin Chang for making this program available to us and writing the search command.

TABLE 2. *Total number of Leo's caregivers' relative clauses included in this study*

Age (Leo)	Total number of utterances in Leo's caregivers' corpus	Total number of Leo's caregivers' relative clauses
2;0	5,377	82 (1·5%)
2;7	4,946	58 (1·2%)
3;2–3;3	4,209	62 (1·5%)
3;9–3;10	4,012	61 (1·5%)
4;10–4;11	4,266	67 (1·6%)
Total	22,810	330 (1·4%)

proportion of relative clauses than Leo's data and their relative constructions are more evenly distributed over the time period of the study.

CODING

All target constructions were coded for three features: (1) the position of the finite verb; (2) the syntactic role of the head; and (3) the syntactic role of the relativized element. We will discuss these features in turn.

The position of the finite verb

Since some verb-second constructions are ambiguous between verb-final and verb-second relative clauses (see above), we divided Leo's relative clauses into three types: (1) verb-final relatives; (2) verb-second relatives; and (3) ambiguous relatives. No other word orders, such as V3, appeared in the data. An example of each type is given (8a–c):

(8) a. Der   Mann, der   Peter geholfen hat.   Verb-final relative
      The-NOM man   who-NOM Peter helped   has
      'The man who helped Peter.'

   b. Der   Mann, der   hat Peter geholfen. Verb-second relative
      The-NOM man   who-NOM/he has Peter helped
      'The man who helped Peter.'

   c. Der   Mann, der   schläft.   Ambiguous
      The-NOM man   who-NOM/he sleeps
      'The man who sleeps.'

The syntactic role of the head

Like English relative clauses, German relative clauses can be attached to any nominal element in the main clause. Five different types of relative

clauses have been distinguished, based on the syntactic role of the head noun: (1) SUBJ-relatives, which are attached to the subject of the main clause; (2) OBJ-relatives, which are attached to the direct object of the main clause; (3) OBL-relatives, which are attached to the noun phrase of a prepositional phrase in the main clause; (4) NP-relatives, which are attached to an isolated head noun; and (5) PN-relatives, which are attached to the predicate nominal of a copular main clause. An example of each type is given in (9a–e):

(9) a. Der   Mann,   <u>der   dir   geholfen hat</u>, SUBJ-relative
       The-NOM man   who-NOM you-DAT helped   has
       heißt   Müller.
       is:called   Müller
       'The man who helped you is called Müller.'

   b. Peter kennt den   Mann, <u>der   dir</u>   OBJ-relative
       Peter knows the-ACC man   who-NOM you-DAT
       <u>geholfen hat</u>.
       helped   has
       'Peter knows the man who helped you.'

   c. Peter spricht mit dem   Mann,   OBL-relative
       Peter talks   to   the-DAT man
       <u>der   dir   geholfen hat</u>.
       who-NOM you-DAT helped   has
       'Peter talks to the man who helped you.'

   d. Der   Mann, <u>der   dir   geholfen hat</u>. NP-relative
       The-NOM man,   who-NOM you-DAT helped   has
       'The man who helped you.'

   e. Das ist der   Mann, <u>der   dir</u>   PN-relative
       That is the-NOM man   who-NOM you-DAT
       <u>geholfen hat</u>.
       helped   has
       'That's the man who helped you.'

The syntactic role of the relativized element

The head of the relative clause must be distinguished from the relativized syntactic role within the relative clause. In German, the relativized syntactic role is indicated by the case feature of the relative pronoun.[6] Five different types can be distinguished: (1) subject relatives, which include a relative pronoun in nominative case; (2) direct-object relatives, which include a

---

[6] If the relative pronoun is ambiguous, word order and semantic features indicate the relativized syntactic role (cf. Diessel & Tomasello, 2005).

relative pronoun in accusative (or dative) case;[7] (3) indirect-object relatives, which include a relative pronoun in dative case and a ditransitive verb; (4) oblique relatives, which include a preposition and a relative pronoun in dative or accusative case;[8] and (5) genitive relatives, which include a relative pronoun in genitive case functioning as attribute of the following noun. In V2-relatives, demonstrative pronouns express the same range of syntactic roles. In order to distinguish the relativized syntactic role from the head of the relative clause, we used capital letters for the syntactic role of the head and small letters for the syntactic role of the relativized element (cf. 10a–e):

(10) a. Der　　　Mann, der　　　　uns　　　gesehen hat.　　subj-relative
　　　The-NOM　man,　who-NOM　us-DAT　seen　　has
　　　'The man who saw us.'

　 b. Der　　　Mann, den　　wir　　　gesehen haben.　obj-relative
　　　The-NOM　man,　who-ACC　we-NOM　seen　　have
　　　'The man who we saw.'

　 c. Der　　　Mann,　　　　　　　　　　　　　　io-relative
　　　The-NOM man,
　　　dem　　　wir　　　das　　　Buch gegeben haben.
　　　who-DAT　we-NOM　the-ACC　book　given　　have
　　　'The man who we gave the book to.'

　 d. Der　　　Mann, dessen　　　Frau uns　　　gen-relative
　　　The-NOM　man,　whose-GEN　wife　us-ACC
　　　gesehen hat.
　　　seen　　has
　　　'The man whose wife has seen us.'

　 e. Der　　　Mann, mit dem　　　wir　　　obl-relative
　　　The-NOM　man　with whom-DAT　we-NOM
　　　gesprochen haben.
　　　talked　　have
　　　'The man to whom we talked.'

RESULTS

Verb-final and verb-second relatives

Leo's data include 465 verb-final relatives and 247 verb-second relatives; in addition, there are 71 relative clauses that are ambiguous between the two

---

[7] There are a few transitive verbs that occur with a dative object (e.g. *der Mann, dem wir geholfen haben* 'The man, whom.DAT we helped have'), but usually the direct object occurs in accusative case.

[8] Alternatively, oblique relatives can include the interrogative *wo* 'where'.

interpretations. That the two types of relative clauses are closely related is suggested by the fact that Leo often switches between them. In fact, as can be seen in (11a–b) and (12a–b), a few relative clauses differ only in the placement of the finite verb. Both pairs of examples occurred in the same transcripts, but were separated from each other by several turns. The co-occurrence of these constructions does not imply that Leo uses them at random. On the contrary, in accordance with the use of these constructions in adult language, he mainly uses V2-relatives in utterances that express new information and are communicatively more important than verb-final relative clauses, which are commonly backgrounded.

(11) a. Und   da   ist der Fisch, …   Zahnschmerzen/ein Wal,
        And   there is the fish …   toothache/a   whale,
        der   hat Zahnschmerzen.
        that-NOM has   toothache-PL
        'And there is the fish, … toothache/a whale, that has toothache.'
        (Leo 2;9)

    b. Wo   ist ein Wal, der   Zahnschmerzen hat?
       Where is a   whale that-NOM toothache-PL   has
       'Where is a whale that has toothache?'
       (Leo 2;9)

(12) a. Im   Schlangenhaus ist sicher auch einer   dabei,
        In.the snake.house   is surely also somebody present
        der   passt   auf.
        who-NOM watches out
        'In the snake house there is surely also somebody present who is watching out.'
        (Leo 4;11)

    b. Bei'n Schlangenhaus ist auch jemand,   der   aufpasst.
       At.the snake.house   is also somebody who-NOM out.watches
       'At the snake house there is also somebody who is watching out.'
       (Leo 4;11)

If we look at the development of the two types of relative clauses, we find that V2-relatives are especially frequent in the early speech samples. As can be seen in Figure 1, up to the age of 2;6, 70% of Leo's relative clauses include the finite verb in second position, 22% have ambiguous word orders and only 8% occur with the finite verb in final position; but in the following years the proportions change dramatically. Between the ages of 4;0 and 5;0, 68% of Leo's relative clauses are verb-final, 27% are verb-second and 5% are ambiguous. This last pattern is comparable to the distribution of the three word order types in the input data, where about two thirds of all
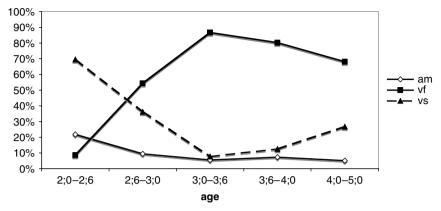

335

Fig. 1. The development of verb-final (vf), verb-second (vs) and ambiguous (am) relative clauses.

relative clauses occur with the finite verb in final position.[9] A χ^2-test, excluding relatives with ambiguous word order, shows that the distributions of verb-second and verb-final relatives are significantly different from one another at different age levels ($\chi^2(4, \; N=712)=144\cdot146, \; p<0\cdot001$), suggesting that the development of German relative clauses involves a crucial shift from verb-second to verb-final constructions, which seems to take place around the age of 3;0. In other words, the data are consistent with our hypothesis that the development of relative clauses originates from main clause structures.

The head of the relative clause

Turning to the external syntactic properties of Leo's relative clauses, we find that they are often headed by an isolated NP. As can be seen in Figure 2, 38·3% of Leo's relatives are NP-relatives, i.e. relative clauses that are attached to an isolated noun phrase. Apart from NP-relatives, PN-relatives (25·3%) and OBJ-relatives (21·3%) are quite common; but OBL-relatives (11·0%) and especially SUBJ-relatives (4·1%) are rare.

Following Diessel & Tomasello (2000), we assume that SUBJ-, OBJ- and OBL-relatives are semantically more complex than NP- and PN-relatives. SUBJ-, OBJ- and OBL-relatives occur in constructions containing two propositions, one in the main clause and another one in the relative clause. But PN- and NP-relatives occur in sentences that only contain a single proposition expressed by the relative clause; the main clause is

[9] According to Birkner (p.c.), V2-relatives account for only about 10% of all relative clauses in spoken adult German.
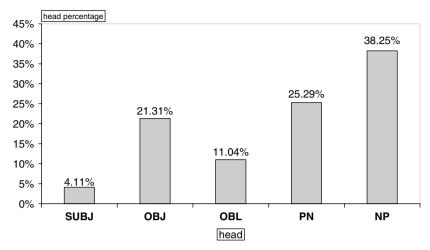

Fig. 2. Percentage of the various head nouns of Leo's relative clauses.

propositionally empty in these constructions (cf. Lambrecht, 1988). Together, PN- and NP-relatives account for 63·5% of the data, which means that the majority of Leo's relative clauses function semantically like simple sentences, just like the majority of children's early relative clauses in English.

If we look at the development of the various types of relative clauses, we find that NP-relatives are especially frequent among Leo's early relative clauses. As can be seen in Figure 3, between the ages of 2;0 and 2;6 more than 80% of Leo's relative clauses are attached to an isolated head noun, but then OBJ-, OBL- and PN-relatives become more frequent, suggesting that his early relative clauses gradually evolve into more complex subordinate constructions. A χ^2-test, excluding relatives that are structurally ambiguous, reveals a significant difference in the distribution of the various heads across age levels (χ^2 (16, $N = 779$) = 134·805, $p < 0.001$), suggesting that the syntactic function of the head is an important determinant of the development of relative clauses.

Note that SUBJ-relatives remain infrequent throughout the study; at no time of the development do they account for more than 5% of Leo's relative clauses. However, compared to children's SUBJ-relatives in English, Leo uses a relatively large proportion of SUBJ-relative clauses. Overall, a mean proportion of only 0·7% are SUBJ-relatives in the English data (cf. Diessel, 2004: Ch. 6), while Leo's SUBJ-relatives account for 4·1% of his relative clauses. This may be due to the fact that SUBJ-relatives are not generally center-embedded in German. A number of studies have argued that English-speaking children tend to avoid SUBJ-relatives because they
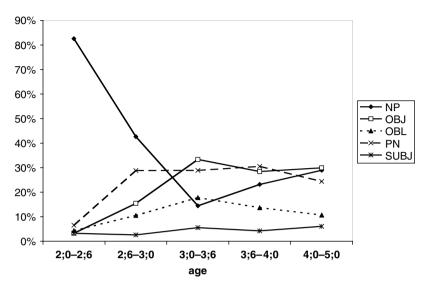

Fig. 3. Changing proportions of the various head nouns.

interrupt the main clause, which is difficult to process (cf. Corrêa, 1995; Kidd & Bavin, 2002). But since German has flexible word order, SUBJ-relatives are not generally center-embedded in the main clause. If the subject occurs at the end of the sentence it can be modified by a right-branching relative clause. Our data support the proposed hypothesis: only 12·5% of Leo's SUBJ-relatives are center-embedded; the rest are right-branching structures that follow the main clause (cf. (13)), suggesting that the relatively large number of SUBJ-relatives is related to the fact that they do not generally interrupt the main clause in German.

There is an alternative explanation that one can derive from a proposal by Limber (1973). According to Limber, English speakers make little use of SUBJ-relatives because the subject is usually a given or topical element, frequently expressed by a pronoun, which does not need a (restrictive) relative clause. If we follow this line of argumentation, one might hypothesize that German speakers use a larger proportion of SUBJ-relatives than English speakers because the subject is less topical in German than in English. We think that this is a plausible explanation. In English, the subject is almost always the topic of the clause, but in German subjects are only topical if they occur prior to other participants at the beginning of the clause. If the subject occurs at the end of the sentence, it does not function as topic and becomes more easily available for a relative clause.

(13) Jetzt fehlt   nur noch eine kleine Karte, <u>wo   Sachen drauf sind.</u>
      Now missing only still a   small card   where things on   are
      'Now only a small card where these things are on is still missing.'
      (Leo 4;10)

Overall, the structure of Leo's relative clauses is similar to the structure of
children's early relative clauses in English, but there are also some
interesting differences. In English, the vast majority of children's relative
clauses are attached to the predicate nominal of a copular clause, but in
Leo's data the majority of the early relative clauses are attached to an
isolated noun phrase. Both constructions are semantically simple sentences,
but serve different discourse–pragmatic functions. PN-relatives characterize
a referent that is established in focus position, whereas Leo's NP-relatives
are usually attached to an NP that resumes a previous discourse referent, as
in (14):

(14) CHI: Ähm, dafür   kriegt sie die **Scheibe**.
            Ah   for.that gets   she the disk
            'Ah for that she will get the disc.'

      MOT: Sie will   die Glocke.
            She wants the bell
            'She wants the bell.'

      CHI: Nein, sagt diese.
            no   says this
            'No, says this one.'

      CHI: Nee, ich leg's einfach mal   hin.
            no   I   put.it just   MODAL down
            'No, I will just put it down.'

      MOT: Leo.
            Leo
            'Leo.'

      CHI: Nein, die **Scheibe**.
            no   the disc
            'No, the disc.'

      MOT: Es ist Wilhelmines Glöckchen.
   it is Wilhelmine's bell
            'It is Wilhelmine's bell.'

      CHI: Die **Scheibe**.
            the disc
            'The disc.'

Fig. 4. Verb-second and verb-final word orders in different types of Leo's relative clauses.

CHI:	Ne **Scheibe**,	die	kann	man	auch darunter
	a disk	that-ACC	can	you-NOM	also under

rollen lassen.
roll   let
'A disc that you can roll under there.'
(Leo 4;6)

Leo's NP-relatives can be seen as topicalization constructions that assert new information about a continuing discourse topic. Their information status is reflected in their word order: as can be seen in Figure 4, most of Leo's NP-relatives occur with verb-second word order, while all other types of relative clauses are more frequent with verb-final word order. Interestingly, the vast majority (72%) of the NP-relatives in the input also occur with verb-second word order.[10]

The relativized syntactic role

Having examined the external properties of Leo's relative clauses, we now turn to their internal syntactic features. Figure 5 shows the percentage of the various relativized syntactic roles in Leo's relative clauses. As can be seen in this figure, the majority of his relatives are subj-relatives; they account for 62% of the data. Twenty percent are obj-relatives, and 17% are

[10] Relative clauses with ambiguous word order have been disregarded.
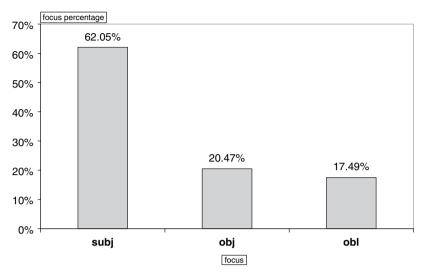

Fig. 5. Percentage of the various relativized syntactic roles of Leo's relative clause.

obl-relatives; io-relatives and gen-relatives do not occur in Leo's data. In the input, there are only a few instances of io- and no gen-relatives.

If we look at the development of the various types of relative clauses, we find that subj-relatives are especially frequent among the earliest relative clauses. As can be seen in Figure 6, the proportion of subj-relatives decreases from 85% between 2;0 and 2;6 to 45% between 3;0 and 3;6 and then remains relatively stable. A χ^2-test, excluding relatives that are structurally ambiguous, reveals a significant difference in the distribution of the relativized syntactic roles across age levels (χ^2 (8, $N = 772) = 70.665$, $p < 0.001$), suggesting that the syntactic function of the relativized syntactic role affects the development of Leo's relative clauses.

Overall, the proportions of the various types of relative clauses in Leo's data are similar to the proportions of children's relative clauses in English. In both languages, the majority of children's relative clauses are subj-relatives, which are especially frequent among the earliest relative clauses. Interestingly, Leo's caregivers' data include a much smaller proportion of subj-relatives than Leo's early speech samples: Only 52% of the caregivers' relative clauses are subj-relatives, 36% are obj-relatives and 11% are obl-relatives. Even if we exclude verb-second relative clauses and only look at the verb-final relatives, the general pattern stays the same: the child produces more subj- than obj-relatives while we find the reverse pattern in his input. Diessel (2004) reports similar proportions of relative clauses in the ambient language of English-speaking children; in
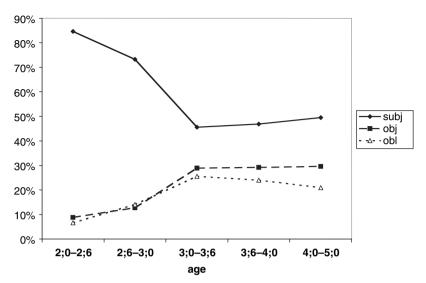

Fig. 6. Changing proportions of the various relativized syntactic roles.

both languages, children produce a much higher proportion of subj-relatives than their caregivers. Why do children use so many subj-relative clauses?

Diessel & Tomasello (2005) argue that English-speaking children have fewer difficulties with subj-relatives than with obj-relatives and obl-relatives because they involve the same word order as simple main clauses. If the subject is relativized, the agent is the first referent of the relative construction, preceding the patient and all other semantic roles, but if the direct object or a prepositional phrase is relativized, the agent is only second after some other semantic role. In other words, in subj-relatives agent and patient occur in the same order as in simple main clauses, but in obj- and obl-relatives the order is reversed.

(15) a. The man who kissed the woman.
       AGENT   VERB PATIENT
    b. The man who the woman kissed.
       PATIENT   AGENT   VERB

Alternatively, one might hypothesize that subj-relatives are dominant in early child language because children tend to use relative clauses with animate head nouns. As Mak, Wietske & Schriefers (2002) have shown, subj-relatives are the only relative clauses that are commonly attached to an animate NP; i.e. obj- and obl-relatives are almost always attached to
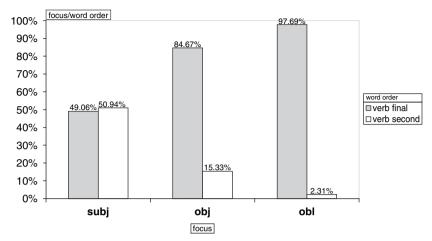

Fig. 7. Verb-second and verb-final word orders in different types of Leo's relative clauses.

inanimate NPs. Kidd, Brandt, Lieven & Tomasello (in press) observed the same tendency in English and German children's early relative clauses.

In German, verb-final relative clauses do not have the same word order as main clauses; but like most German main clauses, subj-relatives express the agent as the first referent of the relative clause, while obj- and obl-relatives include the agent only after some other semantic role (cf. 16a–b). Thus, like subj-relatives in English, subj-relatives in German are similar to main clauses in that they express the agent prior to the other participants. This is in accordance with our hypothesis that children produce their first relative clauses based on their previous knowledge of simple main clauses.

(16) a. Der Mann, der   die Frau   geküsst hat.
         The man   who-NOM the woman kissed has
         AGENT   PATIENT VERB

      b. Der Mann, den   die Frau   geküsst hat
         The man   who-ACC the woman kissed has
         PATIENT   AGENT   VERB

Interestingly, as indicated above, Leo's subj-relatives include a much higher proportion of verb-second word order than his obj- and obl-relatives. As can be seen in Figure 7, subj-relatives commonly occur with both word orders, half of them are verb-final and the other half are verb-second, but obj-relatives and obl-relatives occur primarily with verb-final word order.

343

   If we assume that the different word orders correlate with different types of information (see above), Figure 7 suggests that obj- and obl-relatives are more often backgrounded or pragmatically presupposed than subj-relatives. What could be the reason for this? We suggest that subj-relatives frequently occur with main-clause word order because they express a predication about a referent that typically functions as the agent of the activity denoted by the relative clause (cf. 17), whereas obj-relatives and obl-relatives express a predication about patients, objects, locations and other discourse roles (cf. 18–19). Since naturally occurring conversations tend to focus on human interactions, information about the activities of agents is usually more prominent than information about patients, objects and locations. In other words, subj-relatives tend to be more prominent than obj- and obl-relatives because they are about agents, which is reflected in the frequent use of main-clause word order.

   Note, however, that, apart from the semantic factor, there is also a structural factor that accounts for the large proportion of verb-final word order in obl-relatives. While subj- and obj-relatives are introduced by an anaphoric pronoun that can occur with both word orders (verb-second and verb-final), obl-relatives are often introduced by the question word *wo* 'where', which only occurs with verb-final word order.

(17) Die Biene, die   holt ein Mittagessen.   subj-relative
      The bee   who-NOM/he gets a   lunch
      'The bee who is getting lunch.'
      (Leo 2;4)

(18) Und Tomate in den   Kuchen, den   obj-relative
      And tomato in the-ACC cake   that-ACC
      du   gebacken hast.
      you baked   have
      'And the tomato in (to) the cake that you have baked.'
      (Leo 2;11)

(19) Dieses Haus, wo   die Leute wohnen.   obl-relative
      This   house where the people live
      'This house where the people live.'
      (Leo 2;10)

This analysis is supported by findings from Fox & Thompson (1990), who showed that different structural types of relative clauses tend to have different discourse–pragmatic properties. To simplify, obj- and obl-relatives tend to provide background information about a non-human head, whereas subj-relatives are commonly used to characterize a human or non-human head by new information. Interestingly, Fox & Thompson observed that the characterizing function of subj-relatives is largely

restricted to intransitive clauses; subj-relatives including a transitive verb are rare and tend to provide background information like obj-relatives. In accordance with these findings, Diessel (2004) reports that English-speaking children tend to use intransitive verbs in relative clauses; in particular, the earliest relative clauses are almost exclusively used with intransitive verbs. Like English-speaking children, Leo uses subj-relatives primarily with intransitive verbs. At the age of 2;6, seven out of eight subj-relatives include an intransitive verb; later the proportion of transitive subj-relatives increases, but intransitive subj-relatives remain dominant throughout the time period of this study.

DISCUSSION

To summarize, Leo begins to produce relative clauses shortly after his second birthday. Most of his early relative clauses carry the following features:

1. They are attached to an isolated head noun.
2. They occur with the finite verb in second position.
3. They contain an anaphoric pronoun in nominative case.
4. They usually assert new information.
5. They are intransitive.

The whole structure can be seen as a topicalization construction in which the relative clause functions to characterize the nominal referent of the head noun, which typically resumes a referent from the previous discourse. These topicalization constructions are only a little different from simple main clauses: they include a single verb, occur with the finite verb in second position, denote the agent prior to other participants and tend to provide new information. However, they also share important properties with ordinary relatives: they include an anaphoric pronoun at the beginning of the clause that continues a nominal referent of the immediately preceding NP.

What makes these V2 structures available to the child early in development and prior to verb-final relatives is their similarity to simple main clauses in terms of both word order and information structure. Verb-second constructions are much more frequent in German child-directed speech than verb-final subordinate clauses (cf. Abbot-Smith, Lieven & Stoll, 2005). In addition to similarity, the input seems to be an important determinant of the early production of relative clauses. Although verb-final relatives are overall more frequent than verb-second relatives, Leo's caregivers produced a large number of V2-relatives, providing a model for Leo's early relative clauses. Out of 329 relative clauses in our input sample, 139 (42%) were verb-second.

Like lexical expressions, grammatical constructions are linguistic signs (or symbols) that are connected in mental grammar by associative links indicating structural and semantic relationships between them. As argued in Diessel & Tomasello (2005), children acquire this network in a piecemeal bottom-up fashion, starting with constructions that are only minimally different from simple main clauses, which they already know. In this view, V2-relatives play a key role in the development of German relative clauses because they have properties of both main and relative clauses, which may help the child to bridge the gap between simple sentences and complex relative constructions (for a detailed description of this proposal see Diessel (2004: Ch. 2)).

The development of Leo's relative clauses is parallel to the development of relative clauses in English. In both languages, children's early relative clauses function semantically like simple main clauses; but the source constructions are somewhat different. While English-speaking children produce most of their early relative clauses in focus constructions, consisting of a relative clause and a copular clause (cf. Diessel & Tomasello, 2000), most of Leo's early relative clauses occur in topicalization constructions, consisting of a relative clause and an isolated head noun. However, despite these differences, Leo's data are in accordance with our general hypothesis that the development of relative clauses follows a general cross-linguistic pattern that originates from simple main clauses. Like children's early relative clauses in English, French, Spanish, Hebrew and Indonesian, Leo's early relative clauses develop in an incremental fashion from constructions that are only a little different from simple sentences. It seems that across languages, children draw on their previous knowledge of simple main clauses in the acquisition of relative constructions.

However, we need to acknowledge that, in spontaneous speech, the production of grammatical constructions is determined not only by linguistic complexity but also by communicative factors. For instance, children may not use a particular type of relative clause because the structure is tied to a particular communicative situation that does not occur in parent–child interactions or because there are alternative constructions that are easier to produce. In other words, it is conceivable that children never use a particular construction for communicative reasons, although they have no difficulties in comprehending it.

Since the analysis presented here is based on data from only one child, our results may not generalize to other German-speaking children. However, there is at least one other corpus study of children's early relative clauses that is consistent with our findings. Analyzing 180 relative clauses produced by another German-speaking child called Simone (available on CHILDES), Brandt (2004) observed that V2-relatives are

predominant until the age of 4;0, when the recordings stopped, suggesting that verb-final relatives emerged only later. The other two major findings reported in the current paper were also evident in Simone's data. Like Leo, the child produced a very large number of relative clauses that were headed by isolated NPs and that relativized subjects early in development. As she grew older, the percentage of relatives modifying other kinds of heads (e.g. subjects, objects and predicate nominals) and relativizing objects and obliques increased. The developmental pattern reported here thus seems to hold for other German-speaking children as well as across different languages.
