

# Triviality of the generalized Lau product associated to a Banach algebra homomorphism

Yemon Choi

December 2, 2015

## Abstract

Several papers have, as their *raison d'être*, the exploration of the *generalized Lau product* associated to a homomorphism  $T : B \rightarrow A$  of Banach algebras. In this short note, we demonstrate that the generalized Lau product is isomorphic as a Banach algebra to the usual direct product  $A \oplus B$ . We also correct some misleading claims made about the relationship between this generalized Lau product, and an older construction of Monfared (Studia Mathematica, 2007).

MSc 2010 classification: 46H20

## 1 The generalized Lau product

Motivated by a construction of M. S. Monfared [10], several authors have in recent years written papers on a certain construction, which manufactures a Banach algebra  $A \times_T B$  given a pair of Banach algebras  $(A, B)$  and a continuous algebra homomorphism  $T : B \rightarrow A$ .

**Definition 1.** The underlying Banach space of  $A \times_T B$  is the usual product/sum  $A \oplus B$ ; multiplication is defined by the following rule:

$$(a_1, b_1) \bullet_T (a_2, b_2) = (a_1 a_2 + T(b_1) a_2 + a_1 T(b_2), b_1 b_2)$$

It is clear that  $\bullet_T$  is continuous, and easily verified by hand that it is associative (although this will also follow from the proof of Proposition 3). By renorming if necessary to obtain a submultiplicative norm, one obtains a Banach algebra  $A \times_T B$ .

The construction in Definition 1 has gone by various names: “generalized Lau product”; “the  $T$ -Lau product”; or “the Lau product defined by a Banach algebra morphism”. This last phrase is the one used in [3], which appears to be the earliest occurrence of this construction. Since [3] there have been several papers on the theme of the “generalized Lau product”, by various authors: see [1], [2], [4], [5], [6], [7], [8], [9], [11], [12], [13].

**Remark 2.** In [3] it is claimed that this construction extends that of [10], and that it might have some bearing on extensions of  $C^*$ -algebras in the sense of BDF theory. The second claim is not given clear justification in the article; and the first claim is misleading, to say the least, as will be explained in Section 2).

Unfortunately, the following elementary observation casts doubt on the whole enterprise. We leave the proof to the reader.

**Proposition 3.** *Let  $A \oplus_{\text{alg}} B$  denote the usual sum of Banach algebras, i.e. we equip the Banach spaces  $A \oplus B$  with co-ordinatewise product*

$$(a_1, b_1) \cdot (a_2, b_2) = (a_1 a_2, b_1 b_2).$$

*Define  $\phi : A \times_T B \rightarrow A \oplus_{\text{alg}} B$  by  $\phi(a, b) = (a + T(b), b)$ . Then  $\phi$  is continuous, linear and bijective; and  $\phi((a, b) \bullet_T (c, d)) = \phi(a, b) \cdot \phi(c, d)$ . In particular,  $A \times_T B$  is isomorphic as a Banach algebra to  $A \oplus_{\text{alg}} B$ .*

**Remark 4.** The proof of Proposition 3 was found when the present author was reading the preprint [13], in particular the proof of Proposition 4.1 in that paper. It seems that the authors of [13] noticed something very similar to the isomorphism of Proposition 3, but only in a restricted setting. Similarly, it is observed just after Theorem 4.2 of [6] that there is an isomorphism  $A \times_T B \rightarrow A \oplus_{\text{alg}} B$ , but the authors of [6] only state this in the case where  $A$  and  $B$  are commutative and semisimple, and do not mention that Proposition 3 applies in full generality.

Hopefully, any future attempts to study the generalized Lau product, as defined in Definition 1, will bear in mind that  $A \times_T B \cong A \oplus_{\text{alg}} B$  regardless of the choice of  $T$ . It is a basic theme, when defining a property of Banach algebras, to see how it behaves under forming binary sums/products of algebras. For many of the properties considered in the items of the bibliography, stability of such properties under forming binary sums/products is either known or refuted by old work.

## 2 Comparison with an older construction

It is claimed in [3] that the construction presented there extends the one studied by Monfared in [10]. If this were true, then Monfared's construction would be a special case of Definition 1, and hence would be trivial for the same reason.

In fact, it is *not* true that Monfared's construction is a special case of Definition 1. In this section we shall briefly explain why.

**Definition 5** (Monfared, [10]). Let  $A$  and  $B$  be Banach algebras and let  $\varphi : B \rightarrow \mathbb{C}$  be a character, i.e. a non-zero homomorphism. The *Lau product* of  $A$  and  $B$  with respect to  $\varphi$  is defined to be the Banach algebra whose underlying Banach space is  $A \oplus B$ , equipped with the multiplication operation

$$(a_1, b_1) \bullet_{\varphi} (a_2, b_2) = (a_1 a_2 + \varphi(b_1) a_2 + a_1 \varphi(b_2), b_1 b_2).$$

As observed by Bhatt and Dabhi, it is immediate that when  $A$  has an identity element  $e_A$  and  $\varphi$  is a character on  $B$ , we may define a continuous homomorphism  $T : B \rightarrow A$  by  $T(a) = \varphi(a)e_A$ . If we do this, then the Lau product of  $A$  and  $B$  with respect to  $\varphi$  does indeed coincide with  $A \times_T B$ , and hence by Proposition 3 it is isomorphic to the usual direct product of algebras  $A \oplus_{\text{alg}} B$ .

What seems to have gone unremarked in [3] is that when  $A$  does not have an identity element, Definition 5 is no longer a special case of Definition 1. Indeed, in general the Lau product of  $A$  and  $B$  is not isomorphic as an algebra to  $A \oplus_{\text{alg}} B$ . This is not a new observation — it is implicit in [10] — but for sake of completeness we shall give an example to illustrate this.

**Example 6.** Let  $A$  be an arbitrary Banach algebra. Take  $B = \mathbb{C}$  and let  $\text{id}$  denote the identity map on  $\mathbb{C}$ . It was observed in [10] (and it is also clear from Definition 5) that the corresponding Lau product of  $A$  and  $B$  is isomorphic to  $A^{\sharp}$ , the usual unitization of  $A$ . Observe that  $A \oplus_{\text{alg}} \mathbb{C}$  has an identity element if and only if  $A$  does. Hence, if  $A = c_0(\mathbb{N})$  (for example), then  $A \oplus_{\text{alg}} \mathbb{C}$  cannot be isomorphic to  $A^{\sharp}$ .

A minor variation on the proof of Proposition 3 shows that given  $A, B, \varphi$  as in Definition 5, there is a natural way to identify  $A \times_{\varphi} B$  with a closed, codimension-one subalgebra (not an ideal, in general!) of  $A^{\sharp} \oplus_{\text{alg}} B$ . Given that there continue to be papers exploring the Lau product (as in Definition 5), it therefore seems worthwhile to record the following consequence, whose proof we omit since it is straightforward.

**Proposition 7.** *Let  $Q$  be a property of Banach algebras which is preserved by all isomorphisms of Banach algebras (not just the isometric ones). Suppose also that:*

- *if  $A$  has the property  $Q$ , then so does  $A^\sharp$ ;*
- *if  $A_1$  and  $A_2$  have the property  $Q$ , then so does  $A_1 \oplus_{\text{alg}} A_2$ ;*
- *if  $A$  has the property  $Q$  and  $B$  is a closed subalgebra of  $A$  with finite codimension, then  $B$  has the property  $Q$ .*

*Then the property  $Q$  is preserved by taking Lau products in the sense of Definition 5.*

Note that two examples of such properties are: Arens regularity; and being isomorphic to a closed subalgebra of  $\mathcal{B}(H)$  for some Hilbert space  $H$ .

## Acknowledgements

The author thanks M. Nemati for pointing out the reference [6], and thanks L. Molnar for helpful exchanges. He also thanks the referee for a suggestion which improved Example 6.
